Let \( k[X] = k[x_0, \ldots, x_{n-1}] \) and \( k[Y] = k[y_0, \ldots, y_{n-1}] \) be the polynomial rings in \( n \geq 3 \) variables over a field \( k \) of characteristic zero containing the \( n \)-th roots of unity. Let \( d \) be the cyclotomic derivation of \( k[X] \), and let \( \Delta \) be the factorisable derivation of \( k[Y] \) associated with \( d \), that is, \( d(x_j) = x_{j+1} \) and \( \Delta(y_j) = y_j(y_{j+1} - y_j) \) for all \( j \in \mathbb{Z}_n \). We describe polynomial constants and rational constants of these derivations. We prove, among others, that the field of constants of \( d \) is a field of rational functions over \( k \) in \( n - \varphi(n) \) variables, and that the ring of constants of \( d \) is a polynomial ring if and only if \( n \) is a power of a prime. Moreover, we show that the ring of constants of \( \Delta \) is always equal to \( k[v] \), where \( v \) is the product \( y_0 \cdots y_{n-1} \), and we describe the field of constants of \( \Delta \) in two cases: when \( n \) is power of a prime, and when \( n = pq \).

## Introduction

Throughout this paper \( n \geq 3 \) is an integer, \( k \) is a field of characteristic zero containing the \( n \)-th roots of unity, and \( k[X] = k[x_0, \ldots, x_{n-1}] \) and \( k[Y] = k[y_0, \ldots, y_{n-1}] \) are polynomial rings over \( k \) in \( n \) variables. We denote by \( k(X) = k(x_0, \ldots, x_{n-1}) \) and \( k(Y) = k(y_0, \ldots, y_{n-1}) \) the fields of quotients of \( k[X] \) and \( k[Y] \), respectively. We fix the notations \( d \) and \( \Delta \) for the following two derivations, which we call *cyclotomic derivations*. We denote by \( d \) the derivation of \( k[X] \) defined by

\[
d(x_j) = x_{j+1}, \quad \text{for} \quad j \in \mathbb{Z}_n,
\]

and we denote by \( \Delta \) the derivation of \( k[Y] \) defined by

\[
\Delta(y_j) = y_j(y_{j+1} - y_j), \quad \text{for} \quad j \in \mathbb{Z}_n.
\]
We denote also by $d$ and $\Delta$ the unique extension of $d$ to $k(X)$ and the unique extension of $\Delta$ to $k(Y)$, respectively. We will show that there are some important relations between $d$ and $\Delta$. In this paper we study polynomial and rational constants of these derivations.

In general, if $\delta$ is a derivation of a commutative $k$-algebra $A$, then we denote by $A^\delta$ the $k$-algebra of constants of $\delta$, that is, $A^\delta = \{a \in A; \delta(a) = 0\}$. For a given derivation $\delta$ of $k[X]$, we are interested in some descriptions of $k[X]^\delta$ and $k(X)^\delta$. However, we know that such descriptions are usually difficult to obtain. Rings and fields of constants appear in various classical problems; for details we refer to [5], [6], [27] and [25]. The mentioned problems are already difficult for factorisable derivations. We say that a derivation $\delta : k[X] \to k[X]$ is factorisable if

$$\delta(x_i) = x_i \sum_{j=0}^{n-1} a_{ij} x_j$$

for all $i \in \mathbb{Z}_n$, where each $a_{ij}$ belongs to $k$. Such factorisable derivations and factorisable systems of ordinary differential equations were intensively studied from a long time; see for example [8], [7], [23] and [26]. Our derivation $\Delta$ is factorisable, and the derivation $d$ is monomial, that is, all the polynomials $d(x_0), \ldots, d(x_{n-1})$ are monomials. With any given monomial derivation $\delta$ of $k[X]$ we may associate, using a special procedure, the unique factorisable derivation $D$ of $k[Y]$ (see [16], [28], [22], for details), and then, very often, the problem of descriptions of $k[X]^\delta$ or $k(X)^\delta$ reduces to the same problem for the factorisable derivation $D$.

Consider a derivation $\delta$ of $k[X]$ given by $\delta(x_j) = x_j^{s+1}$ for $j \in \mathbb{Z}_n$, where $s$ is an integer. Such $d$ is called a Jouanolou derivation ([10], [23], [16], [34]). The factorisable derivation $D$, associated with this $\delta$, is a derivation of $k[Y]$ defined by $D(y_j) = y_j(sy_{j+1} - y_j)$, for $j \in \mathbb{Z}_n$. We proved in [16] that if $s \geq 2$ and $n \geq 3$ is prime, then the field of constants of $\delta$ is trivial, that is, $k(X)^\delta = k$. In 2003 H. Žołdek [34] proved the for $s \geq 2$, it is also true for arbitrary $n \geq 3$; without the assumption that $n$ is prime. The central role, in his and our proofs, played some extra properties of the associated derivation $D$. Indeed, for $s \geq 2$, the differential field $(k(X), d)$ is a finite algebraic extension of $(k(Y), \delta)$.

Our cyclotomic derivation $d$ is the Jouanolou derivation with $s = 1$, and the cyclotomic derivation $\Delta$ is the factorisable derivation of $k[Y]$ associated with $d$. In this case $s = 1$, the differential field $(k(X), d)$ is no longer a finite algebraic extension of $(k(Y), \delta)$; the relations between $d$ and $\Delta$ are thus more complicated.

We present some algebraic descriptions of the domains $k[X]^d$, $k[Y]^{\Delta}$, and the fields $k(X)^d$, $k(Y)^{\Delta}$. Note that these rings are nontrivial. The cyclic determinant

$$w = \begin{vmatrix}
  x_0 & x_1 & \cdots & x_{n-1} \\
  x_{n-1} & x_0 & \cdots & x_{n-2} \\
  \vdots & \vdots & \ddots & \vdots \\
  x_2 & x_3 & \cdots & x_0
\end{vmatrix}$$

is a polynomial belonging to $k[X]^d$, and the product $y_0y_1 \cdots y_{n-1}$ belongs to $k[Y]^{\Delta}$. In this paper we prove, among others, that $k(X)^d$ is a field of rational functions over $k$ in $n - \varphi(n)$ variables, where $\varphi$ is the Euler totient function (Theorem 2.9), and that $k[X]^d$ is a polynomial ring over $k$ if and only if $n$ is a power of a prime (Theorem 3.7). The field
$k(X)^d$ is in fact the field of quotients of $k[X]^d$ (Proposition 2.5). We denote by $\xi(n)$ the sum $\sum_{p|n} \frac{n}{p}$, where $p$ runs through all prime divisors of $n$, and we prove that the number of the minimal set of generators of $k[X]^d$ is equal to $\xi(n)$ if and only if $n$ has at most two prime divisors (Corollary 3.13). In particular, if $n = p^iq^j$, where $p \neq q$ are primes and $i, j$ are positive integers, then the minimal number of generators of $k[X]^d$ is equal to $\xi(n) = p^{i-1}q^{j-1}(p + q)$ (Corollary 3.11).

The ring of constants $k[Y]^\Delta$ is always equal to $k[v]$, where $v = y_0y_1 \ldots y_{n-1}$ (Theorem 4.2) and, if $n$ is prime, then $k(Y)^\Delta = k(v)$ (Theorem 5.6). If $n = p^s$, where $p$ is a prime and $s \geq 2$, then $k(Y)^\Delta = k(v, f_1, \ldots, f_{m-1})$ with $m = p^{s-1}$, where $f_1, \ldots, f_{m-1} \in k(Y)$ are homogeneous rational functions such that $v, f_1, \ldots, f_{m-1}$ are algebraically independent over $k$ (Theorem 7.1). A similar theorem we prove for $n = pq$ (Theorem 7.5).

In our proofs we use classical properties of cyclotomic polynomials, and an important role play some results ([11], [12], [32], [33] and others) on vanishing sums of roots of unity.

## 1 Notations and preparatory facts

We denote by $\mathbb{Z}_n$ the ring $\mathbb{Z}/n\mathbb{Z}$, and by $\mathbb{Z}_n^*$ the multiplicative group of $\mathbb{Z}_n$. The indexes of the variables $x_0, \ldots, x_{n-1}$ and $y_0, \ldots, y_{n-1}$ are elements of $\mathbb{Z}_n$. This means, in particular, that if $i, j$ are integers, then $x_i = x_j \iff i \equiv j \pmod{n}$. Throughout this paper $\varepsilon$ is a primitive $n$-th root of unity, and we assume that $\varepsilon \in k$. The letters $\varrho$ and $\tau$ we book for two $k$-automorphisms of the field $k(X) = k(x_0, \ldots, x_{n-1})$, defined by

$$\varrho(x_j) = x_{j+1}, \quad \tau(x_j) = \varepsilon^j x_j \quad \text{for all} \quad j \in \mathbb{Z}_n.$$  

We denote by $u_0, u_1, \ldots, u_{n-1}$ the linear forms in $k[X] = k[x_0, \ldots, x_{n-1}]$, defined by

$$u_j = \sum_{i=0}^{n-1} (\varepsilon^j)^i x_i, \quad \text{for} \quad j \in \mathbb{Z}_n.$$  

If $r$ is an integer and $n \nmid r$, then the sum $\sum_{j=0}^{r-1} (\varepsilon^j)^j$ is equal to 0, and in the other case, when $n \mid r$, this sum is equal to $n$. As a consequence of this fact we obtain, that

$$x_i = \frac{1}{n} \sum_{j=0}^{n-1} (\varepsilon^{-i})^j u_j \quad \text{for all} \quad i \in \mathbb{Z}_n.$$  

Thus, $k[X] = k[u_0, \ldots, u_{n-1}]$, $k(X) = k(u_0, \ldots, u_{n-1})$, and the forms $u_0, \ldots, u_{n-1}$ are algebraically independent over $k$. Moreover, it is easy to check the following equalities.

**Lemma 1.1.** $\tau(u_j) = u_{j+1}$, $\varrho(u_j) = \varepsilon^{-j} u_j$ for all $j \in \mathbb{Z}_n$.

For every sequence $\alpha = (\alpha_0, \alpha_1, \ldots, \alpha_{n-1})$, of integers, we denote by $H_\alpha(t)$ the polynomial in $\mathbb{Z}[t]$ defined by

$$H_\alpha(t) = \alpha_0 + \alpha_1 t^1 + \alpha_2 t^2 + \cdots + \alpha_{n-1} t^{n-1}.$$  

3
An important role in our paper play two subsets of $\mathbb{Z}^n$ which we denote by $G_n$ and $M_n$. The first subset $G_n$ is the set of all sequences $\alpha = (\alpha_0, \ldots, \alpha_n) \in \mathbb{Z}^n$ such that $\alpha_0 + \alpha_1 e^1 + \alpha_2 e^2 + \cdots + \alpha_n e^n = 0$. The second subset $M_n$ is the set of all such sequences $\alpha = (\alpha_0, \ldots, \alpha_n)$ which belong to $G_n$ and the integers $\alpha_0, \ldots, \alpha_n$ are nonnegative, that is, they belong to the set of natural numbers $\mathbb{N} = \{0, 1, 2, \ldots\}$. Let us remember:

$$G_n = \{ \alpha \in \mathbb{Z}^n; H_\alpha(\varepsilon) = 0 \}, \quad M_n = \{ \alpha \in \mathbb{N}^n; H_\alpha(\varepsilon) = 0 \} = G_n \cap \mathbb{N}^n.$$ 

If $\alpha, \beta \in G_n$, then of course $\alpha \pm \beta \in G_n$, and if $\alpha, \beta \in M_n$, then $\alpha + \beta \in M_n$. Thus $G_n$ is an abelian group, and $M_n$ is an abelian monoid with zero $0 = (0, \ldots, 0)$.

The primitive $n$-th root $\varepsilon$ is an algebraic element over $\mathbb{Q}$, and its monic minimal polynomial is equal to the $n$-th cyclotomic polynomial $\Phi_n(t)$. Recall (see for example: [24], [13]) that $\Phi_n(t)$ is a monic irreducible polynomial with integer coefficients of degree $\varphi(n)$, where $\varphi$ is the Euler totient function. This implies that we have the following proposition.

**Proposition 1.2.** Let $\alpha \in \mathbb{Z}^n$. Then $\alpha \in G_n$ if and only if there exists a polynomial $F(t) \in \mathbb{Z}[t]$ such that $H_\alpha(t) = F(t)\Phi_n(t)$.

Put $e_0 = (1, 0, 0, \ldots, 0)$, $e_1 = (0, 1, 0, \ldots, 0)$, $\ldots$, $e_{n-1} = (0, 0, \ldots, 0, 1)$, and let $e = \sum_{i=0}^{n-1} e_i = (1, 1, \ldots, 1)$. Since $\sum_{i=0}^{n-1} e_i = 0$, the element $e$ belongs to $M_n$.

**Proposition 1.3.** If $\alpha \in G_n$, then there exist $\beta, \gamma \in M_n$ such that $\alpha = \beta - \gamma$.

**Proof.** Let $\alpha = (\alpha_0, \ldots, \alpha_n) \in G_n$, and let $r = \min\{\alpha_0, \ldots, \alpha_n\}$. If $r \geq 0$, then $\alpha \in M_n$ and then $\alpha = \beta - \gamma$, where $\beta = \alpha$, $\gamma = 0$. Assume that $r = -s$, where $1 \leq s \in \mathbb{N}$. Put $\beta = \alpha + se$ and $\gamma = se$. Then $\beta, \gamma \in M_n$, and $\alpha = \beta - \gamma$. $\square$

The monoid $M_n$ has an order $\geq$. If $\alpha, \beta \in G_n$, the we write $\alpha \geq \beta$, if $\alpha - \beta \in \mathbb{N}^n$, that is, $\alpha \geq \beta$ if there exists $\gamma \in M_n$ such that $\alpha = \beta + \gamma$. In particular, $\alpha \geq 0$ for any $\alpha \in M_n$. It is clear that the relation $\geq$ is reflexive, transitive and antisymmetric. Thus $M_n$ is a poset with respect to $\geq$.

**Proposition 1.4.** The poset $M_n$ is artinian, that is, if $\alpha^{(1)} \geq \alpha^{(2)} \geq \alpha^{(3)} \geq \ldots$ is a sequence of elements from $M_n$, then there exists an integer $s$ such that $\alpha^{(j)} = \alpha^{(j+1)}$ for all $j \geq s$.

**Proof.** Given an element $\alpha = (\alpha_0, \ldots, \alpha_n) \in M_n$, we put $|\alpha| = \alpha_0 + \cdots + \alpha_n$. Observe that if $\alpha, \beta \in M_n$ and $\alpha > \beta$, then $|\alpha| > |\beta|$. Suppose that there exists an infinite sequence $\alpha^{(1)} > \alpha^{(2)} > \alpha^{(3)} > \ldots$ of elements from $M_n$, and let $s = |\alpha^{(1)}|$. Then we have an infinite sequence $\alpha > |\alpha^{(2)}| > |\alpha^{(3)}| > \cdots > 0$, of natural numbers; a contradiction. $\square$

Let $\alpha \in M_n$. We say that $\alpha$ is a minimal element of $M_n$, if $\alpha \neq 0$ and there is no $\beta \in M_n$ such that $\beta \neq 0$ and $\beta < \alpha$. Equivalently, $\alpha$ is a minimal element of $M_n$, if $\alpha \neq 0$ and $\alpha$ is not a sum of two nonzero elements of $M_n$. It follows from Proposition 1.4 that for any $0 \neq \alpha \in M_n$ there exists a minimal element $\beta$ such that $\beta \leq \alpha$. Moreover, every nonzero element of $M_n$ is a finite sum of minimal elements.
Proposition 1.5. The set of all minimal elements of $M_n$ is finite.

Proof. To deduce this result from Proposition 1.4, Dikson’s Lemma could be used: in any subset $N$ of $\mathbb{N}^n$ there exists a finite number of elements $\{e^{(1)}, \ldots, e^{(s)}\}$ such that $N \subseteq \bigcup (e^{(j)} + \mathbb{N}^n)$.

It is simpler to use classical noetherian arguments. Consider the polynomial ring $R = \mathbb{Z}[z_0, \ldots, z_{n-1}]$. If $\alpha = (\alpha_0, \ldots, \alpha_{n-1})$ is an element from $M_n$, then we denote by $z^\alpha$ the monomial $z_0^{\alpha_0}z_1^{\alpha_1}\cdots z_{n-1}^{\alpha_{n-1}}$. Let $\mathcal{S}$ be the set of all minimal elements of $M_n$, and consider the ideal $A$ of $R$ generated by all elements of the form $z^\alpha$ with $\alpha \in \mathcal{S}$. Since $R$ is noetherian, $A$ is finitely generated; there exist $\alpha^{(1)}, \ldots, \alpha^{(r)} \in \mathcal{S}$ such that $A = \langle z^{\alpha^{(1)}}, \ldots, z^{\alpha^{(r)}} \rangle$. Let $\alpha$ be an arbitrary element from $\mathcal{S}$. Then $z^\alpha \in A$, and then there exist $j \in \{1, \ldots, r\}$ and $\gamma \in \mathbb{N}^n$ such that $z^\alpha = z^\gamma \cdot z^{\alpha^{(j)}} = z^{\gamma + \alpha^{(j)}}$. This implies that $\alpha = \gamma + \alpha^{(j)}$. Observe that $\gamma = \alpha - \alpha^{(j)} \in \mathcal{G}_n \cap \mathbb{N}^n$, and $\mathcal{G}_n \cap \mathbb{N}^n = M_n$, so $\gamma$ belongs to $M_n$. But $\alpha$ is minimal, so $\gamma = 0$, and consequently $\alpha = \alpha^{(j)}$. This means that $\mathcal{S}$ is a finite set equal to $\{\alpha^{(1)}, \ldots, \alpha^{(r)}\}$. $\square$

We denote by $\zeta$, the rotation of $\mathbb{Z}^n$ given by

$$\zeta(\alpha) = (\alpha_{n-1}, \alpha_0, \alpha_1, \ldots, \alpha_{n-2}),$$

for $\alpha = (\alpha_0, \alpha_1, \ldots, \alpha_{n-1}) \in \mathbb{Z}^n$. We have for example: $\zeta(e_j) = e_j+1$ for all $j \in \mathbb{Z}_n$, and $\zeta(e) = e$. The mapping $\zeta : \mathbb{Z}^n \to \mathbb{Z}^n$ is obviously an endomorphism of the $\mathbb{Z}$-module $\mathbb{Z}^n$, and is one-to-one and onto.

Lemma 1.6. Let $\alpha \in \mathbb{Z}^n$. If $\alpha \in \mathcal{G}_n$, then $\zeta(\alpha) \in \mathcal{G}_n$. If $\alpha \in M_n$, then $\zeta(\alpha) \in M_n$. Moreover, $\alpha$ is a minimal element of $M_n$ if and only if $\zeta(\alpha)$ is a minimal element of $M_n$.

Proof. Assume that $\alpha = (\alpha_0, \ldots, \alpha_{n-1}) \in \mathcal{G}_n$. Then $\alpha_0 + \alpha_1 \varepsilon + \cdots + \alpha_{n-1} \varepsilon^{n-1} = 0$. Multiplying it by $\varepsilon$, we have $0 = \alpha_0 \varepsilon + \alpha_1 \varepsilon^2 + \cdots + \alpha_{n-1} \varepsilon^n$. But $\varepsilon^n = 1$, so $\alpha_0 \varepsilon + \alpha_1 \varepsilon^2 + \cdots + \alpha_{n-1} \varepsilon^{n-2} = 0$, and so $\zeta(\alpha) \in \mathcal{G}_n$. This implies also, that if $\alpha \in M_n$, then $\zeta(\alpha) \in M_n$.

Assume now that $\alpha$ is a minimal element of $M_n$ and suppose that $\zeta(\alpha) = \beta + \gamma$, for some $\beta, \gamma \in M_n$. Then we have $\alpha = \zeta^n(\alpha) = \zeta^{-1}(\zeta(\alpha)) = \zeta^{n-1}(\beta) + \zeta^{n-1}(\gamma) = \beta' + \gamma'$, where $\beta' = \zeta^{n-1}(\beta)$ and $\gamma' = \zeta^{n-1}(\gamma)$ belong to $M_n$. Since $\alpha$ is minimal, $\beta' = 0$ or $\gamma' = 0$, and then $\beta = 0$ or $\gamma = 0$. Thus if $\alpha$ is a minimal element of $M_n$, then $\zeta(\alpha)$ is also a minimal element of $M_n$. Moreover, if $\zeta(\alpha)$ is minimal, then $\alpha$ is minimal, because $\alpha = \zeta^{n-1}(\zeta(\alpha))$. $\square$

## 2 The derivation $d$ and its constants

Let us recall that $d : k[X] \to k[X]$ is a derivation such that $d(x_j) = x_{j+1}$, for $j \in \mathbb{Z}_n$.

Proposition 2.1. For each $j \in \mathbb{Z}_n$, the equality $d(u_j) = \varepsilon^{-j} u_j$ holds.
This means that $d$ is a diagonal derivation of the polynomial ring $k[U] = k[u_0, \ldots, u_{n-1}]$ which is equal to the ring $k[X]$. It is known (see for example [25]) that the algebra of constants of every diagonal derivation of $k[U] = k[X]$ is finitely generated over $k$. Therefore, $k[X]^d$ is finitely generated over $k$. We would like to describe a minimal set of generators of the ring $k[X]^d$, and a minimal set of generators of the field $k(X)^d$.

If $\alpha = (\alpha_0, \ldots, \alpha_{n-1}) \in \mathbb{Z}^n$, then we denote by $u^\alpha$ the rational monomial $u_0^{\alpha_0} \cdots u_{n-1}^{\alpha_{n-1}}$. Recall (see the previous section) that $H_\alpha(t)$ is the polynomial $a_0 + a_1 t^{1} + \cdots + a_{n-1} t^{n-1}$ belonging to $\mathbb{Z}[t]$. As a consequence of Proposition 2.1 we obtain

**Proposition 2.2.** $d(u^\alpha) = H_\alpha(\varepsilon^{-1}) u^\alpha$ for all $\alpha \in \mathbb{Z}^n$.

Note that $\varepsilon^{-1}$ is also a primitive $n$-th root of unity. Hence, by Proposition 1.2, we have the equivalence $H_\alpha(\varepsilon^{-1}) = 0 \iff H_\alpha(\varepsilon) = 0$, and so, by the previous proposition, we see that if $\alpha \in \mathbb{Z}^n$, then $d(u^\alpha) = 0 \iff \alpha \in G_n$, and if $\alpha \in \mathbb{N}^n$, then $d(u^\alpha) = 0 \iff \alpha \in \mathcal{M}_n$. Moreover, if $F = b_1 u^{\alpha(1)} + \cdots + b_r u^{\alpha(r)}$, where $b_1, \ldots, b_r \in k$ and $\alpha(1), \ldots, \alpha(r)$ are pairwise distinct elements of $\mathbb{N}^n$, then $d(F) = 0$ if and only if $d\left(b_i u^{\alpha(i)}\right) = 0$ for every $i = 1, \ldots, r$. Hence, $k[X]^d$ is generated over $k$ by all elements of the form $u^\alpha$ with $\alpha \in \mathcal{M}_n$. We know (see the previous section), that every nonzero element of $\mathcal{M}_n$ is a finite sum of minimal elements of $\mathcal{M}_n$. Thus we have the following next proposition.

**Proposition 2.3.** The ring of constants $k[X]^d$ is generated over $k$ by all the elements of the form $u^\beta$, where $\beta$ is a minimal element of the monoid $\mathcal{M}_n$.

In the next section we will prove some additional facts on the minimal number of generators of the ring $k[X]^d$. Now, let us look at the field $k(X)^d$.

**Proposition 2.4.** The field of constants $k(X)^d$ is generated over $k$ by all elements of the form $u^\gamma$ with $\gamma \in G_n$.

**Proof.** Let $L$ be the subfield of $k(X)$ generated over $k$ by all elements of the form $u^\gamma$ with $\gamma \in G_n$. It is clear that $L \subseteq k(X)^d$. We will prove the reverse inclusion. Assume that $0 \neq f \in k(X)^d$. Since $k(X) = k(U)$, we have $f = A/B$, where $A, B$ are coprime polynomials in $k[U]$. Put

$$A = \sum_{\alpha \in S_1} a_\alpha u^\alpha, \quad B = \sum_{\beta \in S_2} b_\beta u^\beta,$$

where all $a_\alpha, b_\beta$ are nonzero elements of $k$, and $S_1, S_2$ are some subsets of $\mathbb{N}^n$. Since $d(f) = 0$, we have the equality $Ad(B) = d(A)B$. But $A, B$ are relatively prime, so $d(A) = \lambda A, d(B) = \Lambda B$ for some $\lambda \in k[U]$. Comparing degrees, we see that $\lambda \in k$. Moreover, by Proposition 2.2, we deduce that $d(u^\alpha) = \lambda u^\alpha$ for all $\alpha \in S_1$, and also
d(u^β) = λu^β for all β ∈ S_2. This implies that if δ_1, δ_2 ∈ S_1 ∪ S_2, then d(u^{δ_1-δ_2}) = 0.

In fact, d(u^{δ_1-δ_2}) = d\left(\frac{u^{δ_1}}{u^{δ_2}}\right) = \frac{1}{u^{δ_2}} d(u^{δ_1}) u^{δ_2} - d(u^{δ_2}) = \frac{1}{u^{δ_2}} (λu^{δ_1} u^{δ_2} - λu^{δ_1} u^{δ_2}) = 0.

This means, that if δ_1, δ_2 ∈ S_1 ∪ S_2, then δ_1 - δ_2 ∈ G_n. Fix an element δ from S_1 ∪ S_2. Then all α - δ, β - δ belong to G_n, and we have

\[ f = \frac{A}{B} = \sum a_\alpha u^\alpha \sum b_\beta u^\beta = \frac{u^{\delta} \sum a_\alpha u^\alpha}{u^{\delta} \sum b_\beta u^\beta} = \frac{\sum a_\alpha u^{\alpha - \delta}}{\sum b_\beta u^{\beta - \delta}}, \]

and hence, f ∈ L. □

Let us recall (see Proposition 1.3) that every element of the group G_n is a difference of two elements from the monoid M_n. Using this fact and the previous propositions we obtain

**Proposition 2.5.** The field k(X)^d is the field of quotients of the ring k[X]^d.

Now we will prove that k(X)^d is a field of rational functions over k, and its transcendental degree over k is equal to n - ϕ(n), where ϕ is the Euler totient function. For this aim look at the cyclotomic polynomial Φ_n(t). Assume that

\[ Φ_n(t) = c_0 + c_1 t + \cdots + c_{ϕ(n)} t^{ϕ(n)}. \]

All the coefficients c_0, ..., c_{ϕ(n)} are integers, and a_0 = a_{ϕ(n)} = 1. Put m = n - ϕ(n) and

\[ γ_0 = \left( c_0, c_1, \ldots, c_{ϕ(n)}, 0, \ldots, 0 \right). \]

Note that γ_0 ∈ Z^n, and H_{γ_0}(t) = Φ_n(t). Consider the elements γ_0, γ_1, ..., γ_{m-1} defined by

\[ γ_j = \zeta^j(γ_0), \quad \text{for} \quad j = 0, 1, \ldots, m - 1. \]

Observe that H_{γ_j}(t) = Φ_n(t) t^j for all j ∈ {0, ..., m - 1}. Since Φ_n(ε) = 0, we have H_{γ_j}(ε) = 0, and so, the elements γ_0, ..., γ_{m-1} belong to G_n.

**Lemma 2.6.** The elements γ_0, ..., γ_{m-1} generate the group G_n.

**Proof.** Let α ∈ G_n. It follows from Proposition 1.2, that H_α(t) = F(t)Φ_n(t), for some F(t) ∈ Z[t]. Then obviously deg F(t) < m. Put F(t) = b_0 + b_1 t + ... + b_{m-1} t^{m-1}, with b_0, ..., b_{m-1} ∈ Z. Then we have

\[ H_α(t) = b_0 (Φ_n(t) t^0) + b_1 (Φ_n(t) t^1) + \cdots + b_{m-1} (Φ_n(t) t^{m-1}) \]

\[ = \sum_{j=0}^{m-1} b_j H_{γ_j}(t) + \cdots + b_{m-1} H_{γ_{m-1}}(t), \]

and this implies that α = b_0 γ_0 + b_1 γ_1 + ... + b_{m-1} γ_{m-1}. □

Consider now the rational monomials w_0, ..., w_{m-1} defined by

\[ w_j = u^{γ_j} = u_0^{c_0} u_1^{c_1} u_2^{c_2} \cdots u_{ϕ(n)}^{c_{ϕ(n)}} \]

for j = 0, 1, ..., m - 1, where m = n - ϕ(n). Each w_j is a rational monomial with respect to u_0, ..., u_{n-1} of the same degree equals to ϕ_n(1) = c_0 + c_1 + ... + c_{ϕ(n)}. It is known (see for example [13]) that ϕ_n(1) = p if n is power of a prime number p, and ϕ_n(1) = 1 in all other cases. As each u_j is a homogeneous polynomial in k[X] of degree 1, we have:
Lemma 2.8. The elements $w_0, \ldots, w_{m-1}$ are algebraically independent over $k$.

Proof. Let $A$ be the $n \times m$ Jacobi matrix $[a_{ij}]$, where $a_{ij} = \frac{\partial w_i}{\partial u_j}$ for $i = 0, 1, \ldots, n-1$, $j = 0, 1, \ldots, m-1$. It is enough to show that $\text{rank}(A) = m$ (see for example [9]). Observe that $\frac{\partial w_0}{\partial u_0} = c_0 u_0^{-n} a_1^c \cdots u_{\varphi(n)}^{c_{\varphi(n)}} \neq 0$ (because $c_0 = 1$), and $\frac{\partial w_j}{\partial u_0} = 0$ for $j \geq 1$. Moreover, $\frac{\partial w_i}{\partial u_1} \neq 0$ and $\frac{\partial w_i}{\partial u_1} = 0$ for $j \geq 2$, and in general, $\frac{\partial w_i}{\partial u_i} \neq 0$ and $\frac{\partial w_i}{\partial u_i} = 0$ for all $i, j = 0, \ldots, m-1$ with $j > i$. This means, that the upper $m \times m$ matrix of $A$ is a triangular matrix with a nonzero determinant. Therefore, $\text{rank}(A) = m$. \(\square\)

Thus, we proved the following theorem.

Theorem 2.9. The field of constants $k(X)^d$ is a field of rational functions over $k$ and its transcendental degree over $k$ is equal to $m = n - \varphi(n)$, where $\varphi$ is the Euler totient function. More precisely,

$$k(X)^d = k\left(w_0, \ldots, w_{m-1}\right),$$

where the elements $w_0, \ldots, w_{m-1}$ are as above.

Now we will describe all constants of $d$ which are homogeneous rational functions of degree zero. Let us recall that a nonzero polynomial $F$ is homogeneous of degree $r$, if all its monomials are of the same degree $r$. We assume that the zero polynomial is homogeneous of arbitrary degree. Homogeneous polynomials are also homogeneous rational functions, which (in characteristic zero) are defined in the following way. Let $f = f(x_0, \ldots, x_{n-1}) \in k(X)$ We say that $f$ is homogeneous of degree $s \in \mathbb{Z}$, if in the field $k(t, x_0, \ldots, x_{n-1})$ the equality $f(tx_0, tx_1, \ldots, tx_{n-1}) = t^s \cdot f(x_0, \ldots, x_{n-1})$ holds It is easy to prove (see for example [25] Proposition 2.1.3) the following equivalent formulations of homogeneous rational functions.

Proposition 2.10. Let $F,G$ be nonzero coprime polynomials in $k[X]$ and let $f = F/G$. Let $s \in \mathbb{Z}$. The following conditions are equivalent.

1. The rational function $f$ is homogeneous of degree $s$.
2. The polynomials $F$, $G$ are homogeneous of degrees $p$ and $q$, respectively, where $s = p - q$.
3. $x_0 \frac{\partial f}{\partial x_0} + \cdots + x_{n-1} \frac{\partial f}{\partial x_{n-1}} = sf$.

Equality (3) is called the Euler formula. In this paper we denote by $E$ the Euler derivation of $k(X)$, that is, $E$ is a derivation of $k(X)$ defined by $E(x_j) = x_j$ for all $j \in \mathbb{Z}_n$. As usually, we denote by $k(X)^E$ the field of constants of $E$. Observe that, by Proposition 2.10, a rational function $f \in k(X)$ belongs to $k(X)^E$ if and only if $f$ is homogeneous of degree zero. In particular, the set of all homogeneous rational functions of degree zero is a
subfield of $k(X)$. It is obvious that the quotients $\frac{x_1}{x_0}, \ldots, \frac{x_{n-1}}{x_0}$ belong to $k(X)^E$, and they are algebraically independent over $k$. Moreover, $k(X)^E = k(\frac{x_1}{x_0}, \ldots, \frac{x_{n-1}}{x_0})$. Therefore, $k(X)^E$ is a field of rational functions over $k$, and its transcendence degree over $k$ is equal to $n-1$. Put $q_j = \frac{x_j+1}{x_j}$ for all $j \in \mathbb{Z}_n$. In particular, $q_{n-1} = \frac{x_0}{x_0}$. The elements $q_0, \ldots, q_{n-1}$ belong to $k(X)^E$ and moreover, $\frac{x_j}{x_0} = q_0 q_1 \cdots q_{j-1}$ for $j = 1, \ldots, n - 1$. Thus we have the following equality.

**Proposition 2.11.** $k(X)^E = k(\frac{x_1}{x_0}, \frac{x_2}{x_1}, \ldots, \frac{x_{n-1}}{x_{n-2}}, \frac{x_0}{x_{n-1}})$.

Now consider the field $k(X)^{d, E} = k(X)^d \cap k(X)^E$.

**Lemma 2.12.** Let $d_1, d_2 : k(X) \to k(X)$ be two derivations. Assume that $K(X)^{d_i} = k(c, b_1, \ldots, b_s)$, where $c, b_1, \ldots, b_s$ are algebraically independent over $k$ elements from $k(X)$ such that $d_2(b_1) = \cdots = d_2(b_s) = 0$ and $d_2(c) \neq 0$. Then $k(X)^{d_1} \cap k(X)^{d_2} = k(b_1, \ldots, b_s)$.

**Proof.** Put $L = k(b_1, \ldots, b_s)$. Observe that $k(X)^{d_1} = L(c)$, and $c$ is transcendental over $L$. Let $0 \neq f \in k(X)^{d_1} \cap k(X)^{d_2}$. Then $f = \frac{F(c)}{G(c)}$, where $F(t), G(t)$ are coprime polynomials in $L[t]$. We have: $d_2(F(c)) = F'(c)d_2(c)$, $d_2(G(c)) = G'(c)d_2(c)$, where $F'(t), G'(t)$ are derivatives of $F(t), G(t)$, respectively. Since $d_2(f) = 0$, we have

$$0 = d_2(F(c))G(c) - d_2(G(c))F(c) = \left(F'(c)G(c) - G'(c)F(c)\right)d_2(c),$$

and so, $(F'G - G'F)(c) = 0$, because $d_2(c) \neq 0$. Since $c$ is transcendental over $L$, we obtain the equality $F'(t)G(t) = G'(t)F(t)$ in $L[t]$, which implies that $F(t)$ divides $F'(t)$ and $G(t)$ divides $G'(t)$ (because $F(t), G(t)$ are relatively prime), and comparing degrees we deduce that $F'(t) = G'(t) = 0$, that is, $F(t) \in L$ and $G(t) \in L$. Thus the elements $F(c), G(c)$ belong to $L$ and so, $f = \frac{F(c)}{G(c)}$ belongs to $L$. Therefore, $k(X)^{d_1} \cap k(X)^{d_2} \subseteq L$. The reverse inclusion is obvious. \qed

Let us return to the rational functions $w_0, \ldots, w_{m-1}$. We know (see Proposition 2.7) that they are homogeneous of the same degree. Put: $d_1 = d$, $d_2 = E$, $c = w_0$ and $b_j = \frac{w_j}{w_0}$ for $j = 1, \ldots, m - 1$. Then, as a consequence of Lemma 2.12, we obtain the following proposition.

**Proposition 2.13.** $k(X)^{d, E} = k(\frac{w_1}{w_0}, \ldots, \frac{w_{m-1}}{w_0})$.

Since $w_0, \ldots, w_{m-1}$ are algebraically independent over $k$ (see Lemma 2.8), the quotients $\frac{w_1}{w_0}, \ldots, \frac{w_{m-1}}{w_0}$ are also algebraically independent over $k$. Thus, $k(X)^{d, E}$ is a field of rational functions and its transcendental degree over $k$ is equal to $n - \varphi(n) - 1$, where $\varphi$ is the Euler totient function. In particular, if $n$ is prime, then $n - \varphi(n) - 1 = 0$ and we obtain:

**Corollary 2.14.** $k(X)^{d, E} = k \iff n$ is a prime number.
3 Numbers of minimal elements

Let \( \mathcal{F} \) be the set of all the minimal elements of the monoid \( \mathcal{M}_n \), and denote by \( \nu(n) \) the cardinality of \( \mathcal{F} \). We know, by Proposition 1.5, that \( \nu(n) < \infty \). We also know (see Proposition 2.3) that the ring \( k[X]^d \) is generated over \( k \) by all the elements of the form \( u^\beta \), where \( \beta \in \mathcal{F} \). But \( k[X] \) is equal to the polynomial ring \( k[U] = k[u_0, \ldots, u_{n-1}] \), so \( k[X]^d \) is generated over \( k \) by a finite set of monomials with respect to the variables \( u_0, \ldots, u_{n-1} \).

It is clear that if \( \beta, \gamma \) are distinct elements from \( \mathcal{F} \), then \( u^\beta \nmid u^\gamma \) and \( u^\gamma \nmid u^\beta \). This implies that no monomial \( u^\beta, \beta \in \mathcal{F} \) belongs to the algebra generated by other \( u^\gamma, \gamma \in \mathcal{F} \), \( u^\gamma \nmid u^\beta \). Thus, \( \{u^\beta; \beta \in \mathcal{F}\} \) is a minimal set of generators of \( k[X]^d \).

Moreover, \( \{u^\beta; \beta \in \mathcal{F}\} \) is a set on generators of \( k[X]^d \) with the minimal number of elements according to the following proposition.

**Proposition 3.1.** Let \( f_1, \ldots, f_s \) be polynomials in \( k[X] \). If \( k[X]^d = k[f_1, \ldots, f_s] \), then \( s \geq \nu(n) \).

**Proof.** As the \( u^\beta \) are monomials in the \( u \)'s, they constitute a Gröbner base for the ideal \( I \) generated in \( k[X] \) by \( k[X]^d \). This basis is minimal for any admissible order, for example the lexicographical one.

Making a head reduction of the \( f_i \), a new head-reduced system of generators appears, maybe with less than \( s \) elements. Thus, without loss of generality, we can suppose that the system \( (f_1, \ldots, f_s) \) is head-reduced, which means that the leading monomial of one \( f_i \) does not belong to the multiplicative monoid generated by the other leading monomials.

The leading monomials of the various \( f_i \) are \( u^\alpha \) for some \( \alpha \in \mathcal{M}_n \).

The exponents \( \alpha \) are minimal in the sub-monoid they generate, but this sub-monoid has to be \( \mathcal{M}_n \) itself. \( \square \)

In this section we prove, among others, that \( k[X]^d \) is a polynomial ring over \( k \) if and only if \( n \) is a power of a prime number. Moreover, we present some additional properties of the number \( \nu(n) \), which are consequences of known results on vanishing sums of roots of unity; see for example [12], [30], [32] and [33], where many interesting facts and references on this subject can be found.

We denote by \( \xi(n) \) the sum \( \sum_{p|n} \frac{n}{p} \), where \( p \) runs through all prime divisors of \( n \). Note that if \( a, b \) are positive coprime integers, then \( \xi(ab) = a\xi(b) + \xi(a)b \).

First we show that the computation of \( \nu(n) \) can be reduced to the case when \( n \) is square-free. For this aim let us denote by \( n_0 \) the largest square-free factor of \( n \), and by \( n' \) the integer \( n/n_0 \). Then \( \varphi(n) = n'\varphi(n_0) \), \( \Phi_n(t) = \Phi_{n_0}(t^{n'}) \) (see for example [24]), and \( \xi(n) = n'\xi(n_0) \).

Assume now that \( n = mc \), where \( m \geq 2, c \geq 2 \) are integers. For a given sequence \( \gamma = (\gamma_0, \ldots, \gamma_{m-1}) \in \mathbb{Z}^m \), consider the sequence

\[
\overline{\gamma} = \left( \begin{array}{c}
\gamma_0, 0, \ldots, 0, \gamma_1, 0, \ldots, 0, \ldots, \gamma_{m-1}, 0, \ldots, 0,
\end{array} \right)_{c-1}
\]

This sequence is an element of \( \mathbb{Z}^n \), and it is easy to prove the following lemma.
Lemma 3.2. \( \gamma \in G_n \iff \gamma \in G_m \), and \( \gamma \in M_n \iff \gamma \in M_m \). Moreover, \( \gamma \) is a minimal element of \( M_n \iff \gamma \) is a minimal element of \( M_m \).

Using the above notations, we have:

**Proposition 3.3.** \( \nu(n) = n' \nu(n_0) \), for all \( n \geq 3 \).

**Proof.** If \( n' = 1 \) then this is clear. Assume that \( n' \geq 2 \). Let \( \alpha = (\alpha_0, \ldots, \alpha_{n-1}) \) be an element of \( M_m \). For every \( j \in \{0, 1, \ldots, n' - 1\} \), let us denote:

\[
f_j(t) = \sum_{i=0}^{n_0-1} \alpha_{i+n^j} t^{i n^j}, \quad \beta_j = (\alpha_{0n^j}, \alpha_{1n^j}, \ldots, \alpha_{(n_0-1)n^j}),
\]

Note that \( f_j(t) \in \mathbb{Z}[t] \) and \( \beta_j \in \mathbb{N}^{n_0} \). Consider the elements \( \overline{\beta}_0, \overline{\beta}_1, \ldots, \overline{\beta}_{n'-1} \), introduced before Lemma 3.2 for \( m = n_0 \) and \( c = n' \). Observe that

\[ (*) \quad \alpha = \overline{\beta}_0 + \zeta(\overline{\beta}_1) + \zeta^2(\overline{\beta}_2) + \cdots + \zeta^{n'-1}(\overline{\beta}_{n'-1}) \]

where \( \zeta \) is the rotation of \( \mathbb{Z}^n \), as in Section 1. Denote also by \( f(t) \) the polynomial \( H_\alpha(t) = \alpha_0 + \alpha_1 t + \cdots + \alpha_{n-1} t^{n-1} \), that is, \( f(t) = \sum_{j=0}^{n'-1} f_j(t) \). It follows from Proposition 1.2, that \( f(t) = g(t) \Phi_n(t) \) for some \( g(t) \in \mathbb{Z}[t] \).

For every \( j \in \{0, 1, \ldots, n'-1\} \), denote by \( A_j \) the set of polynomials \( F(t) \in \mathbb{Z}[t] \) such that the degrees of all nonzero monomials of \( F(t) \) are congruent to \( j \) modulo \( n' \). We assume that the zero polynomial also belongs to \( A_j \). It is clear that each \( A_j \) is a \( \mathbb{Z} \)-module, \( A_i A_j \subseteq A_{i+j} \) for \( i, j \in \mathbb{Z}_{n'} \), and \( \mathbb{Z}[t] = \bigoplus_{j \in \mathbb{Z}_{n'}} A_j \). Thus, we have a gradation on \( \mathbb{Z}[t] \) with respect to \( \mathbb{Z}_{n'} \). We will say that it is the \( n' \)-gradation, and the decompositions of polynomials with respect to this gradation we will call the \( n' \)-decompositions.

Let \( g(t) = g_0(t) + g_1(t) + \cdots + g_{n'-1}(t) \) be the \( n' \)-decomposition of \( g(t) \); each \( g_j(t) \) belongs to \( A_j \). Since \( \Phi_n(t) = \Phi_{n_0}(t^{n'}) \), \( \Phi_n(t) \in A_0 \) and

\[
f(t) = g_0(t) \Phi_n(t) + g_1(t) \Phi_n(t) + \cdots + g_{n'-1}(t) \Phi_n(t),
\]

is the \( n' \)-decomposition of \( f(t) \). But the previous equality \( f(t) = \sum f_j(t) \) is also the \( n' \)-decomposition of \( f(t) \), so we have \( f_j(t) = g_j(t) \Phi_n(t) \) for all \( j \in \mathbb{Z}_{n'} \).

Put \( \eta = \varepsilon^{n'} \). Then \( \eta \) is a primitive \( n_0 \)-th root of unity and, for every \( j \in \mathbb{Z}_{n'} \),

\[
\sum_{i=0}^{n_0-1} \alpha_{i+n^j} \eta^i = \varepsilon^{-j} f_j(\varepsilon) = \varepsilon^{-j} g_j(\varepsilon) \Phi_n(\varepsilon) = \varepsilon^{-j} g_j(\varepsilon) \cdot 0 = 0.
\]

This means that each \( \beta_j \) is an element of \( M_{n_0} \).

Assume now that the above \( \alpha \) is a minimal element of \( M_n \). Then, by \((*)\), we have \( \alpha = \zeta^j(\overline{\beta}_j) \) for some \( j \in \{0, \ldots, n' - 1\} \). Then \( \overline{\beta}_j = \zeta^{n'-j}(\alpha) \) and so, \( \overline{\beta}_j \) is (by Lemma 1.6) a minimal element of \( M_m \), and this implies, by Lemma 3.2, that \( \beta_j \) is a minimal element of \( M_{n_0} \). Thus, every minimal element \( \alpha \) of \( M_n \) is of the form \( \alpha = \zeta^j(\overline{\beta}) \), where \( j \in \{0, \ldots, n' - 1\} \) and \( \beta \) is a minimal element of \( M_{n_0} \), and it is clear that this presentation is unique. This means, that \( \nu(n) \leq n' \cdot \nu(n_0) \).
Assume now that $\beta$ is a minimal element of $\mathcal{M}_{n_0}$. Then we have $n'$ pairwise distinct sequences $\beta, \zeta(\beta), \zeta^2(\beta), \ldots, \zeta^{n'-1}(\beta)$, which are (by Lemmas 1.6 and 3.2) minimal elements of $\mathcal{M}_n$. Hence, $\nu(n) \geq n' \cdot \nu(n_0)$. Therefore, $\nu(n) = n' \cdot \nu(n_0)$. $\Box$

If $p$ is prime, then $\nu(p) = 1$; the constant sequence $e = (1, 1, \ldots, 1)$ is a unique minimal element of $\mathcal{M}_p$. In this case $k[X]^d$ is the polynomial ring $k[w]$, where $w = u_0 \ldots u_{p-1}$ is the cyclic determinant of the variables $x_0, \ldots, x_{p-1}$ (see Introduction). In particular, if $p = 3$, then $k[x_0, x_1, x_2]^d = k[x_0^3 + x_1^3 + x_2^3 - 3x_0x_1x_2]$. Using Proposition 3.3 and its proof we obtain:

**Proposition 3.4.** Let $n = p^s$, where $s \geq 1$ and $p$ is a prime number. Then $\nu(n) = \xi(n) = p^{s-1}$, and the ring of constants $k[X]^d$ is a polynomial ring over $k$ in $p^{s-1}$ variables.

Assume now that $p$ is a prime divisor of $n$. Denote by $n_p$ the integer $n/p$, and consider the sequences

$$E_i^{(p)} = \sum_{j=0}^{p-1} e_{i+jn_p},$$

for $i = 0, 1, \ldots, n_p - 1$. Recall that $e_0 = (1, 0, \ldots, 0)$, \ldots, $e_{n-1} = (0, 0, \ldots, 0, 1)$ are the basic elements of $\mathbb{Z}^n$. Observe that each $E_i^{(p)}$ is equal to $\zeta^i \left( E_0^{(p)} \right)$, where $\zeta$ is the rotation of $\mathbb{Z}^n$. Observe also that $E_0^{(p)} = \bar{e}$, where in this case $e = (1, 1, \ldots, 1) \in \mathbb{Z}^n$ and $\bar{e}$ is the element of $\mathbb{Z}^n$ introduced before Lemma 3.2 for $m = p$ and $c = n_p$. But $e$ is a minimal element of $\mathcal{M}_p$, so we see, by Lemmas 3.2 and 1.6, that each $E_i^{(p)}$ is a minimal element of $\mathcal{M}_n$. We will say that such $E_i^{(p)}$ is a *standard* minimal element of $\mathcal{M}_n$. It is clear that if $i, j \in \{0, 1, \ldots, n_p - 1\}$ and $i \neq j$, then $E_i^{(p)} \neq E_j^{(p)}$. Observe also that, for every $i$, we have $\left| E_i^{(p)} \right| = p$. This implies, that if $p \neq q$ are prime divisors of $n$, then $E_i^{(p)} \neq E_j^{(q)}$ for all $i \in \{0, \ldots, n_p - 1\}$, $j \in \{0, 1, \ldots, n_q - 1\}$. Assume that $p_1, \ldots, p_s$ are all the prime divisors of $n$. Then, by the above observations, the number of all standard minimal elements of $\mathcal{M}_n$ is equal to $n_{p_1} + \cdots + n_{p_s}$, that is, it is equal to $\xi(n)$. Hence, we proved the following proposition.

**Proposition 3.5.** $\nu(n) \geq \xi(n)$, for all $n \geq 3$.

For a proof of the next result we need the following lemma.

**Lemma 3.6.** If $n$ is divisible by two distinct primes, then $\xi(n) + \varphi(n) > n$.

**Proof.** Since $\xi(n) = n' \xi(n_0)$, $\varphi(n) = n' \varphi(n_0)$ and $n = n' n_0$ we may assume that $n$ is square-free. Let $n = p_1 \cdots p_s$, where $s \geq 2$ and $p_1, \ldots, p_s$ are distinct primes. If $s = 2$, then the equality is obvious. Assume that $s \geq 3$, and that the equality is true for $s - 1$. Put $p = p_s$, $m = p_1 \cdots p_{s-1}$. Then $m$ is square-free, $n = mp$, $\gcd(m, p) = 1$, $\xi(m) + \varphi(m) > m$ and moreover, $\varphi(m) < m$. Hence, $\xi(n) + \varphi(n) = p\xi(m) + \xi(p)m + \varphi(p)\varphi(m) = p\xi(m) + m + (p - 1)\varphi(m) > p\xi(m) + p\varphi(m) > pm = n$. and hence, by an induction, $\xi(n) + \varphi(n) > n$. $\Box$
Theorem 3.7. The ring of constants \( k[X]^d \) is a polynomial ring over \( k \) if and only if \( n \) is a power of a prime number.

Proof. Assume that \( n \) is divisible by two distinct primes, and suppose that \( k[X]^d \) is a polynomial ring of the form \( k[f_1, \ldots, f_s] \), where \( f_1, \ldots, f_s \in k[X] \) are algebraically independent over \( k \). Then, by Proposition 3.1, we have \( s \geq \nu(n) \). The polynomials \( f_1, \ldots, f_s \) belong to the field \( k(X)^d \), and we know, by Theorem 2.9, that the transcendental degree of this field over \( k \) is equal to \( n - \varphi(n) \). Hence, \( s \leq n - \varphi(n) \). But \( \nu(n) \geq \xi(n) \) (Proposition 3.5) and \( \xi(n) > n - \varphi(n) \) (Lemma 3.6), so we have a contradiction: \( s \geq \nu(n) \geq \xi(n) > n - f(n) \). This means, that if \( n \) is divisible by two distinct primes, then \( k[X]^d \) is not a polynomial ring over \( k \). Now this theorem follows from Proposition 3.4. \( \square \)

It is well known (see for example [2]) that all coefficients of the cyclotomic polynomial \( \Phi_n(t) \) are nonnegative if and only if \( n \) is a power of a prime. Thus, we proved that \( k[X]^d \) is a polynomial ring over \( k \) if and only if all coefficients of \( \Phi_n(t) \) are nonnegative.

In our next considerations we will apply the following theorem of Rédéi, de Bruijn and Schoenberg.

Theorem 3.8 ([29], [4], [31]). The standard minimal elements of \( \mathcal{M}_n \) generate the group \( \mathcal{G}_n \).

Known proofs of the above theorem used usually techniques of group rings. Lam and Leung [12] gave a new proof using induction and group-theoretic techniques.

Now, let us assume that \( n = pq \), where \( p \neq q \) are primes. In this case, Lam and Leung [12] proved that \( \nu(n) = p + q \). We will give a new elementary proof of this fact. Note that in this case \( n_p = q \) and \( n_q = p \). Put \( P_i = E_i^{(q)} \) for \( i = 0, 1, \ldots, p - 1 \), and \( Q_j = E_j^{(p)} \) for \( j = 0, \ldots, q - 1 \). We have \( p + q \) elements \( P_0, \ldots, P_{p-1}, Q_0, \ldots, Q_{q-1} \), which are the standard minimal elements of \( \mathcal{M}_{pq} \).

Lemma 3.9. For every \( \beta \in \mathcal{M}_{pq} \) there exist nonnegative integers \( a_0, \ldots, a_{p-1}, b_0, \ldots, b_{q-1} \) such that \( \beta = a_0P_0 + \cdots + a_{p-1}P_{p-1} + b_0Q_0 + \cdots + b_{q-1}Q_{q-1} \).

Proof. Let \( \beta \in \mathcal{M}_{pq} \). Then \( \beta \in \mathcal{G}_{pq} \) and, by Theorem 3.8, we have an equality \( \beta = \sum a_iP_i + \sum b_jQ_j \), for some integers \( a_0, \ldots, a_{p-1}, b_0, \ldots, b_{q-1} \). Since \( \sum_{i=0}^{p-1} P_i = e = \sum_{j=0}^{q-1} Q_j \), we may assume that \( b_{q-1} = 0 \). Let us recall that \( P_i = \sum_{j=0}^{q-1} e_{jp+i} \) for \( i = 0, \ldots, p - 1 \), and \( Q_j = \sum_{i=0}^{p-1} e_{iq+j} \) for \( j = 0, \ldots, q - 1 \). Thus, we have

\[
\beta = \sum_{i=0}^{p-1} \sum_{j=0}^{q-1} \left( a_i e_{jp+i} + b_j e_{iq+j} \right).
\]

Every number \( m \) from \( \{0, 1, \ldots, pq - 1\} \) has a unique presentation in the form \( m = sp + r \) with \( s \in \{0, \ldots, q-1\} \), \( r \in \{0, \ldots, p-1\} \), and it has also a unique presentation \( m = s_1q + r_1 \) with \( s_1 \in \{0, \ldots, p-1\} \), \( r_1 \in \{0, \ldots, q-1\} \). Hence, it follows from (1) that

\[
a_i + b_j \geq 0 \quad \text{for all} \quad i \in \{0, \ldots, p-1\}, \quad j \in \{0, \ldots, q-1\}.
\]

13
But \( b_{q-1} = 0 \), so \( a_i \geq 0 \) for all \( i = 0, \ldots, p - 1 \). If all the numbers \( b_0, \ldots, b_{q-2} \) are also nonnegative, then we are done.

Assume that among \( b_0, \ldots, b_{q-2} \) there exists a negative integer, and consider the number \( b_s = \min \{ b_0, \ldots, b_{q-2} \} \). Then \( s \in \{ 0, \ldots, q - 2 \} \) and \( -b_s > 0 \). Put \( A = \{ 0, \ldots, q - 1 \} \setminus \{ s \} \). Using again the equality \( \sum_{i=0}^{p-1} P_i = \sum_{j=0}^{q-1} Q_j \), we have: \( b_s Q_s = \sum_{i=0}^{p-1} b_s P_i + \sum_{j \in A} (-b_s) Q_j \). Hence,

\[
\beta = \sum_{i=0}^{p-1} (a_i + b_s) P_i + \sum_{j \in A} (b_j - b_s) Q_j + (-b_s) Q_{q-1}.
\]

By (2), each \( a_i + b_s \) is nonnegative. Moreover \( b_s \leq b_s \) for all \( j \notin A \), and \( -b_s > 0 \). Therefore, in the above presentation all the coefficients are nonnegative integers. \( \square \)

**Theorem 3.10 ([12]).** Let \( n = p^i q^j \), where \( p \neq q \) are primes and \( i, j \) are positive integers. Then \( \nu(n) = \xi(n) = p^{i-1} q^{j-1} (p + q) \). In other words, the monoid \( M_n \) has exactly \( p^{i-1} q^{j-1} (p + q) \) minimal elements, and all its minimal elements are standard.

**Proof.** Let \( n = pq \), and \( B = \{ P_0, \ldots, P_{p-1}, Q_0, \ldots, Q_{q-1} \} \). We know that every element of \( B \) is a standard minimal element of \( M_{pq} \), and that all these elements are pairwise distinct. Moreover, it follows from Lemma 3.9 that every \( \beta \in M_{pq} \), which is a minimal element of \( M_{pq} \), belongs to \( B \). Hence, \( \nu(pq) = p + q = \xi(pq) \). This implies, by the equality \( \xi(n) = n' \xi(n_0) \) Proposition 3.3, that \( \nu(n) = \xi(n) \) for all \( n \) of the form \( p^i q^j \). \( \square \)

As a consequence of Theorem 3.10 and Proposition 3.1 we obtain:

**Corollary 3.11.** Let \( n = p^i q^j \), where \( p \neq q \) are primes and \( i, j \) are positive integers. Then the minimal number of generators of the ring of constants \( k[X]^d \) is equal to \( \xi(n) = p^{i-1} q^{j-1} (p + q) \).

We already know that if \( n \) is divisible by at most two distinct primes, then every minimal element of \( M_n \) is standard. It is well known (see for example [12], [33], [30]) that in all other cases always exist nonstandard minimal elements. For instance, Lam and Leung [12] proved that if \( n \) is divisible by three primes \( p_1 < p_2 < p_3 \), then the equality \( a_1 a_2 + a_3 = 0 \), where \( a_j = \sum_{i=1}^{p_j-1} \varepsilon^{in_p} \) for \( j = 1, 2, 3 \), is of the form \( H_\alpha(\varepsilon) = 0 \), where \( \alpha \) is a nonstandard minimal element of \( M_n \). There are also other examples. Assume that \( n = p_1 \cdots p_s \), where \( p_1, \ldots, p_s \) are distinct primes, and denote by \( U \) the set of all numbers from \( \{ 1, 2, \ldots, n - 1 \} \) which are relatively prime to \( n \). If \( s \geq 3 \) is odd, then

\[
\gamma = e_0 + \sum_{u \in U} e_u
\]

is a nonstandard minimal element of \( M_n \). This element \( \gamma \) belongs to \( M_n \), because the sum of all primitive \( n \)-th roots of unity is equal to \( \mu(n) \), where \( \mu \) is the M\"obius function (see for example [15], [20]). The minimality of \( \gamma \) follows from the known fact (see for example [3]) that if \( n \) is square-free, then all the primitive \( n \)-th roots of unity form a
basis of \( \mathbb{Q}(\varepsilon) \) over \( \mathbb{Q} \). Observe also that \( |\gamma| = \varphi(n) + 1 \neq p_i \) for all \( i = 1, \ldots, s \), so \( \gamma \) is nonstandard.

If \( s \geq 4 \) is even, then put \( p = p_s \), \( n' = p_1 \cdots p_{s-1} \), and let \( U' \) the set of all numbers from \( \{1, 2, \ldots, n' - 1\} \) which are relatively prime to \( n' \). Then \( \varepsilon^p \) is a primitive \( n' \)-th root of unity and, using similar arguments, we see that

\[
\gamma' = e_0 + \sum_{v \in U'} e_v p^i.
\]

is a nonstandard minimal element of \( M_n \). Thus we have the following result of Lam and Leung.

**Theorem 3.12 ([12]).** If \( n \geq 3 \) is an integer, then \( \nu(n) = \xi(n) \) if and only if \( n \) has at most two prime divisors.

Now, as a consequence of the previous considerations, we obtain:

**Corollary 3.13.** The number of a minimal set of generators of \( k[X]^d \) is equal to \( \xi(n) \) if and only if \( n \) has at most two prime divisors.

Note that in our examples all nonzero coefficients of the minimal (standard or nonstandard) elements of \( M_n \) were equal to 1. Recently, John P. Steinberger [33] gave the first explicit constructions of nonstandard minimal elements of \( M_n \) (for some \( n \)) with coefficients greater than 1 (indeed containing arbitrary large coefficients). He gave at the same time an answer to an old question of H.W. Lenstra Jr. [14] concerning this subject.

## 4 Polynomial constants of \( \Delta \)

Let us recall that \( \Delta \) is the derivation of \( k[Y] \) given by \( \Delta(y_j) = y_j (y_{j+1} - y_j) \) for \( j \in \mathbb{Z}_n \), where \( k[Y] = k[y_0, \ldots, y_{n-1}] \). It is a homogeneous derivation, that is, all the polynomials \( \Delta(y_0), \ldots, \Delta(y_{n-1}) \) are homogeneous of the same degree. Put \( v = y_0 y_1 \cdots y_{n-1} \). Observe that \( v \in k[Y]^2 \). In this section we will prove that \( k[Y]^{\Delta} = k[v] \). For this aim we first study Darboux polynomials of \( \Delta \).

We say that a nonzero polynomial \( F \in k[Y] \) is a **Darboux polynomial** of \( \Delta \), if \( F \) is homogeneous and there exists a polynomial \( \Lambda \in k[Y] \) such that \( \Delta(F) = \Lambda F \). Such a polynomial \( \Lambda \) is uniquely determined and we say that \( \Lambda \) is the **cofactor** of \( F \). Some basic properties of Darboux polynomials of arbitrary homogeneous derivations one can find for example in [23], [21] or [25]. Note that if \( F, G \in k[Y] \) and \( FG \) is a Darboux polynomial of \( \Delta \), then \( F, G \) are also Darboux polynomials of \( \Delta \) ([23], [25]). It is obvious that in our case each cofactor \( \Lambda \) is of the form \( \lambda_0 y_0 + \lambda_1 y_1 + \cdots + \lambda_{n-1} y_{n-1} \), where the coefficients \( \lambda_0, \ldots, \lambda_{n-1} \) belong to \( k \). We say that a Darboux polynomial is **strict** if it is not divisible by any of the variables \( y_0, \ldots, y_{n-1} \). The following important proposition is a special case of Proposition 3 from our paper [17]. For a sake of completeness we repeat its proof.

**Proposition 4.1.** Let \( F \in k[Y] \setminus k \) be a strict Darboux polynomial of \( \Delta \) and let \( \Lambda = \lambda_0 y_0 + \cdots + \lambda_{n-1} y_{n-1} \) be its cofactor. Then all \( \lambda_i \) are integers and they belong to the interval \([-r, 0] \), where \( r = \deg F \). Moreover, two of the \( \lambda_i \) at least are different from 0.
Proof. As $F$ is strict, for any $i$, the polynomial $F_i = F_{y_i=0}$ (that we get by evaluating $F$ in $y_i = 0$) is a nonzero homogeneous polynomial with the same degree $r$ in $n - 1$ variables (all but $y_i$). Evaluating the equality $\Delta(F) = \Lambda F$ at $y_{n-1} = 0$ we obtain
\[
(*) \quad \sum_{i=0}^{n-3} y_i(y_{i+1} - y_i) \frac{\partial F_{n-1}}{\partial y_i} - y_{n-2}^2 \frac{\partial F_{n-1}}{\partial y_{n-2}} = \left( \sum_{i=0}^{n-2} \lambda_i y_i \right) F_{n-1}.
\]
Let $r_0$ be the degree of $F_{n-1}$ with respect to $y_0$. Then obviously $0 \leq r_0 \leq r$. Consider now $F_{n-1}$ as a polynomial in $k[y_1, \ldots, y_{n-2}][y_0]$. Balancing monomials of degree $r_0 + 1$ in the equality $(*)$ gives $\lambda_0 = -r_0$. The same results hold for all coefficients of the cofactor $\Lambda$.

We already proved that all $\lambda_i$ are integers and $-r \leq \lambda_i \leq 0$. Moreover, we proved that $|\lambda_i|$ is the degree of $F_{i-1}$ with respect to $y_i$ (for any $i \in \mathbb{Z}_n$). Thus $\lambda_i = 0$ means that the variable $y_{i-1}$ appears in every monomial of $F$ in which $y_i$ appears. Then, if all $\lambda_i$ vanish, the product of all variables divides the nonzero polynomial $F$, a contradiction with the fact that $F$ is strict. In the same way, if all $\lambda_i$ but one vanish, the variable corresponding to the nonzero coefficient divides $F$, once again a contradiction. \(\Box\)

**Theorem 4.2.** The ring of constants $k[Y]^\Delta$ is equal to $k[v]$, where $v = y_0y_1 \ldots, y_{n-1}$.

**Proof.** The inclusion $k[v] \subseteq k[Y]^\Delta$ is obvious. We will prove the reverse inclusion. For every Darboux polynomial $F$ of $\Delta$, we denote by $\Lambda(F)$ the cofactor of $F$. Then we have $\Delta(F) = \Lambda(F) \cdot F$, and $\Lambda(F) = \lambda_0y_0 + \cdots + \lambda_{n-1}y_{n-1}$, where the coefficients $\lambda_0, \ldots, \lambda_{n-1}$ are uniquely determined. In this case we denote by $\Gamma(F)$ the sum $\lambda_0 + \lambda_1 + \cdots + \lambda_{n-1}$. In particular, the variables $y_0, \ldots, y_{n-1}$ are Darboux polynomials of $\Delta$, and $\Lambda(y_i) = y_{i+1} - y_j$, $\Gamma(y_j) = 0$, for any $j \in \mathbb{Z}_n$. It follows from Proposition 4.1 that if a Darboux polynomial $F$ is strict and $F \not\in k$, then $\Gamma(F)$ is an integer, and $\Gamma(F) \leq -2$. Note also that if $F, G$ are Darboux polynomials of $\Delta$, then $FG$ is a Darboux polynomial of $\Delta$, and then
\[
\Lambda(FG) = \Lambda(F) + \Lambda(G) \quad \text{and} \quad \Gamma(FG) = \Gamma(F) + \Gamma(G).
\]
Assume now that $F$ is a nonzero polynomial belonging to $k[Y]^\Delta$. We will show that $F \in k[v]$. Since the derivation $\Delta$ is homogeneous we may assume that $F$ is homogeneous. Thus $F$ is a Darboux polynomial of $\Delta$ and its cofactor is equal to 0. Let us write this polynomial in the form
\[
F = y_0^{\beta_0} y_1^{\beta_1} \cdots y_{n-1}^{\beta_{n-1}} \cdot G,
\]
where $\beta_0, \ldots, \beta_{n-1}$ are nonnegative integers, and $G$ is a nonzero from $K[Y]$ which is not divisible by any of the variables $y_0, \ldots, y_{n-1}$. Then $G$ is a strict Darboux polynomial of $\Delta$. Let us suppose that $G \not\in k$. Then $\Gamma(G) \leq -2$ (by Proposition 4.1), and we have a contradiction:
\[
0 = \Gamma(F) = \sum_{j=0}^{n-1} \beta_j \Gamma(y_j) + \Gamma(G) = \sum_{j=0}^{n-1} \beta_j \cdot 0 + \Gamma(G) = \Gamma(G) \leq -2.
\]
Thus $F$ is a monomial of the form $by^\beta = by_0^{\beta_0} y_1^{\beta_1} \cdots y_{n-1}^{\beta_{n-1}}$, with some nonzero $b \in k$. But $\Delta(F) = 0$, so $\beta_0(y_1 - y_0) + \beta_1(y_2 - y_1) + \cdots + \beta_{n-1}(y_n - y_{n-1}) = 0$, and so $\beta_0 = \beta_1 = \cdots = \beta_{n-1} = c$, for some $c \in \mathbb{N}$. Now we have $F = by^\beta = b(y_0 \cdots y_{n-1})^c = bv^c$, and hence $F \in k[v]. \Box$
5 The mappings $@$ and $\tau$

In this section we show that the derivations $d$ and $\Delta$ have certain additional properties, and we present some specific relations between these derivations.

Let us fix the following two notations:

$$a = \left( \frac{x_1}{x_0}, \frac{x_2}{x_1}, \ldots, \frac{x_{n-1}}{x_{n-2}}, \frac{x_0}{x_{n-1}} \right) \quad \text{and} \quad v = y_0y_1 \cdots y_{n-1}.$$

We already know, by Proposition 2.11 and Theorem 4.2, that $k(X)^E = k(a)$ and $k[Y]^{\Delta} = k[v]$.

**Lemma 5.1.** Let $F \in k[Y]$. If $F(a) = 0$, then there exists a polynomial $G \in k[Y]$ such that $F = (v - 1)G$.

**Proof.** First note that if $b = (b_0, \ldots, b_{n-1})$ is an element of $k^n$ such that the product $b_0b_1 \cdots b_{n-1}$ equals 1, then $b$ is of the form $b = \left( \frac{c_1}{c_0}, \frac{c_2}{c_1}, \ldots, \frac{c_{n-1}}{c_{n-2}}, \frac{c_n}{c_{n-1}} \right)$, for some nonzero elements $c_0, \ldots, c_n$ from $k$. In fact, put: $c_0 = 1$, $c_1 = b_0$, $c_2 = b_0b_1$, $\ldots$, $c_{n-1} = b_0b_1 \cdots b_{n-2}$.

Let $P = v - 1$, and let $A$ be the ideal of $\overline{k}[Y] = \overline{k}[y_0, \ldots, y_{n-1}]$ generated by $P$, where $\overline{k}$ is the algebraic closure of $k$. Observe that, for any $b \in \overline{k}$, if $P(b) = 0$, then (by the assumption and the above note) $F(b) = 0$. This means, by the Nullstellensatz, that some power of $F$ belongs to the ideal $A$. But $A$ is a prime ideal, so $F \in A$ and so, there exists a polynomial $G \in \overline{k}[Y]$ such that $F = (v - 1)G$. Since $F, v - 1$ belong to $k[Y]$, it is obvious that $G$ also belongs to $k[Y]$. $\square$

**Lemma 5.2.** Let $F$ be a nonzero homogeneous polynomial in $k[Y]$, then $F(a) \neq 0$.

**Proof.** Suppose that $F(a) = 0$. Then, by Lemma 5.1, $F = (v - 1)G$, for some $G \in k[Y]$. As $F$ is homogeneous, the polynomials $v - 1$ and $G$ are also homogeneous; but it is a contradiction, because $v - 1$ is not homogeneous. $\square$

Let us denote by $S$ the multiplicative subset $\{ F \in k[Y]; \ F(a) \neq 0 \}$ and consider the quotient ring

$$A = S^{-1}k[Y].$$

Every element of this ring is of the form $F/G$, where $F, G \in k[Y]$ and $G(a) \neq 0$. It is a local ring with the unique maximal ideal $I = \{ \frac{F}{G} \in A; \ F(a) = 0 \}$. It follows from Lemma 5.1 that $I = (v - 1)A$. Observe that $\Delta(A) \subseteq A$ and $\Delta(I) \subseteq I$, so $\Delta$ is a derivation of $A$ and $I$ is a differential ideal of $A$.

If $f \in A$, then $f(a)$ is well defined, and it is a homogeneous rational function of degree zero, that is, $f(a) \in k(X)^E$. Thus we have a $k$-algebra homomorphism from $A$ to $k(X)^E$. This homomorphism we will denote by $@$. So we have:

$$@ : A \rightarrow k(X)^E, \quad @ (f) = f(a) \quad \text{for} \quad f \in A.$$

In particular, $@ (v) = 1$, and $@ (y_j) = \frac{x_{j+1}}{x_j}$ for $j \in \mathbb{Z}_n$. These equalities imply that $@$ is surjective. Note also that $\ker @ = I$, so the field $k(X)^E$ is isomorphic to the factor ring $A/I$. Moreover, as a consequence of Lemma 5.2 we have:
Proposition 5.3. If $f \in k(Y)$ is homogeneous and $\@ (f) = 0$, then $f = 0$.

Note also the next important proposition.

Proposition 5.4. $d \circ \@ = \@ \circ \Delta$, that is, $d (f(a)) = (\Delta(f))(a)$ for $f \in A$.

Proof. It is enough to prove that the above equality holds in the case when $f = y_j$ with $j \in \mathbb{Z}_n$. Let $f = y_j$, $j \in \mathbb{Z}_n$. Then:

$$
\begin{align*}
    d \left( f(a) \right) &= d \left( \frac{x_{j+1}}{x_j} \right) = \frac{d(x_{j+1})x_j - d(x_j)x_{j+1}}{x_j^2} = \frac{x_{j+1}^2 - x_j^2}{x_j^2} \left( \frac{x_{j+1} - x_j}{x_j} \right) \\
    &= (y_j(y_{j+1} - y_j))(a) = (\Delta(y_j))(a) = (\Delta(f))(a).
\end{align*}
$$

This completes the proof. □

Corollary 5.5. Let $f \in A$. If $\Delta(f) = 0$, then $d(\@ (f)) = 0$.

Proof. $d(\@ (f)) = \@ (\Delta(f)) = \@ (0) = 0$ (by Proposition 5.4). □

Now we are ready to prove the following theorem.

Theorem 5.6. If $n$ is a prime number, then $k(Y)^\Delta = k(v)$, where $v = y_0 y_1 \cdots y_{n-1}$.

Proof. Put $P = v - 1$. Note that $\Delta(P) = 0$. Let $0 \neq f = \frac{F}{G} \in k(Y)$, where $F, G$ are nonzero, coprime polynomials in $k[Y]$, and assume that $\Delta(f) = 0$. We will show, using an induction with respect to $\deg F + \deg G$, that $f \in k(v)$.

If $\deg F + \deg G = 0$, then $f \in k$, so $f \in k(v)$. Assume that $\deg F + \deg G = r > 0$.

If $P$ divides $F$, then $F = F'P$, for some $F' \in k[Y]$, and then $\Delta \left( \frac{F'}{G} \right) = \frac{1}{P} \Delta \left( \frac{F}{G} \right) = 0$ with $\deg F' + \deg G < r$. Then, by induction, $\frac{F'}{G} \in k(v)$ and this implies that $\frac{F}{G} \in k(v)$, because $\frac{F}{G} = P^E \frac{E}{G}$ and $P \in k(v)$. We use the same argument in the case when $P$ divides $G$.

Now we may assume that $P \nmid F$ and $P \nmid G$. In this case, by Lemma 5.1, the quotient $\frac{E}{G}$ belongs to $A$, and $\@ \left( \frac{E}{G} \right) \neq 0$. Moreover, we may assume that $\deg F \geq \deg G$ (in the opposite case we consider $G/F$ instead of $F/G$).

Since $\Delta(f) = 0$, we have (by Corollary 5.5) $\@ (f) \in k(X)^d \cap k(X)^E = k(X)^{d,E}$. But $n$ is prime so, by Corollary 2.14, $k(X)^{d,E} = k$. Therefore, $\@ \left( \frac{E}{G} \right) = c$, for some nonzero $c \in k$. Thus we have

$$
0 = \@ \left( \frac{E}{G} \right) - c = \@ \left( \frac{E - cG}{G} \right) = \@ \left( \frac{F - cG}{G} \right),
$$

and hence, $\@ (F - cG) = 0$. If $F - cG = 0$, then $\frac{E}{G} = c \in k(v)$. Assume that $F - cG \neq 0$. Then, by Lemma 5.1, $F - cG = H \cdot P$, for some nonzero $H \in k[Y]$. As $\gcd(F, G) = 1$, we have $\gcd(H, G) = 1$. Observe that $\Delta \left( \frac{H}{G} \right) = 0$. In fact, $\Delta \left( \frac{H}{G} \right) = \frac{1}{P} \Delta \left( \frac{P H}{G} \right) = \frac{1}{P} \Delta \left( \frac{E - cG}{G} \right) = \frac{1}{P} \Delta \left( \frac{E}{G} \right) - c = \frac{1}{P} \Delta \left( \frac{E}{G} \right) = 0$. It is clear that $\deg H + \deg G < \deg F + \deg G$. Hence, by induction, the quotient $\frac{H}{G}$ belongs to $k(v)$. But

$$
f = \frac{E}{G} = \left( \frac{E}{G} \right) - c = \frac{F - cG}{G} + c = P \frac{H}{G} + c,
$$

18
so \( f \in k(v) \). We proved that \( k(Y)^\Delta \subseteq k(v) \). The reverse inclusion is obvious. □

Let us recall (see Theorem 4.2), that the ring of constants \( k[Y]^\Delta \) is always equal to \( k[v] \). Thus, if \( n \) is prime, then \( k(Y)^\Delta \) is the field of quotients of \( k[Y]^\Delta \). In a general case a similar statement is not true. For example, if \( n = 4 \), then the rational function

\[
\frac{2y_0y_2 - y_2y_3 - y_0y_1}{y_1y_2 + y_0y_3 - 2y_1y_3}
\]

belongs to \( k(Y)^\Delta \) and it is not in \( k(v) \).

Let us recall (see Section 1) that \( \tau \) is an automorphism of \( k(X) \) defined by

\[
\tau(x_j) = \varepsilon^j x_j \quad \text{for all} \quad j \in \mathbb{Z}_n.
\]

We say that a rational function \( f \in k(X) \) is \( \tau \)-homogeneous, if \( f \) is homogeneous in the ordinary sense and \( \tau(f) = \varepsilon^s f \) for some \( s \in \mathbb{Z}_n \). In this case we say that \( s \) is the \( \tau \)-degree of \( f \) and we write \( \text{deg}_\tau(f) = s \). Note that \( \text{deg}_\tau(f) \) is an element of \( \mathbb{Z}_n \).

Let \( \alpha = (\alpha_0, \ldots, \alpha_{n-1}) \in \mathbb{Z}^n \). As usually, we denote by \( x^\alpha \) the rational monomial \( x_0^{\alpha_0} \cdots x_{n-1}^{\alpha_{n-1}} \), and by \( |\alpha| \) the sum \( \alpha_0 + \cdots + \alpha_{n-1} \). Moreover, we denote by \( \sigma(\alpha) \) the element from \( \mathbb{Z}_n \) defined by

\[
\sigma(\alpha) = 0\alpha_0 + 1\alpha_1 + 2\alpha_2 + \cdots + (n-1)\alpha_{n-1} \pmod{n}.
\]

Let us recall (see Section 1) that \( \varrho : k(X) \to k(X) \) is a field automorphism, defined by \( \varrho(x_j) = x_{j+1} \) for all \( j \in \mathbb{Z}_n \). It is very easy to check that:

**Proposition 5.7.** Every rational monomial \( x^\alpha \), where \( \alpha \in \mathbb{Z}^n \), is \( \tau \)-homogeneous and its \( \tau \)-degree is equal to \( \sigma(\alpha) \). Moreover, if \( 0 \neq f \in k(X) \) and \( f \) is \( \tau \)-homogeneous, then \( \varrho(f) \) is also \( \tau \)-homogeneous, and \( \text{deg}_\tau \varrho(f) \equiv \text{deg}_\tau f + \text{deg} f \pmod{n} \).

The derivation \( d \) has the following additional properties.

**Proposition 5.8.** \( \tau d \tau^{-1} = \varepsilon d \).

**Proof.** It is enough to show that \( \tau d(x_j) = \varepsilon d(\tau(x_j)) \) for \( j \in \mathbb{Z}_n \). Let us verify:

\[
\tau d(x_j) = \tau(x_{j+1}) = \varepsilon^{j+1} x_{j+1} = \varepsilon \cdot \varepsilon^j d(x_j) = \varepsilon d(\varepsilon^j x_j) = \varepsilon d(\tau(x_j)). \quad \square
\]

**Proposition 5.9.** Let \( f \in k(X) \). If \( f \) is \( \tau \)-homogeneous, then \( d(f) \) is \( \tau \)-homogeneous and \( \text{deg}_\tau d(f) = 1 + \text{deg}_\tau f \).

**Proof.** Assume that \( f \) is \( \tau \)-homogeneous and \( s = \text{deg}_\tau f \). Since the derivation \( d \) is homogeneous and \( f \) is homogeneous in the ordinary sense, \( d(f) \) is also homogeneous in the ordinary sense. Moreover, by the previous proposition, we have: \( \tau(d(f)) = \varepsilon d(\tau(f)) = \varepsilon d(\varepsilon^s f) = \varepsilon^{s+1} d(f) \), so \( d(f) \) is \( \tau \)-homogeneous and \( \text{deg}_\tau d(f) = s + 1 \). □

**Proposition 5.10.** Let \( F \in k[X] \) be a Darboux polynomial of \( d \). If \( F \) is \( \tau \)-homogeneous, then \( d(F) = 0 \).
\textbf{Proof.} Assume that }d(F) = bF \text{ with } b \in k[X], \text{ } F \text{ is homogeneous in the ordinary sense, and } \tau(F) = \varepsilon^s F. \text{ Then } b \in k, \text{ and we have } \varepsilon d(F) = \varepsilon^{-s} \varepsilon d(\varepsilon^s F) = \varepsilon^{-s} \varepsilon d(\tau(F)) = \varepsilon^{-s} \tau(d(F)) = \varepsilon^{-s} \tau(bF) = b \varepsilon^{-s} \tau(F) = b \varepsilon^{-s} \varepsilon^s F = b F = d(F). \text{ Hence, } (\varepsilon - 1) d(F) = 0. \text{ But } \varepsilon \neq 1, \text{ so } d(F) = 0. \square

\textbf{Proposition 5.11.} Let } f = \frac{P}{Q}, \text{ where } P, Q \text{ are nonzero coprime polynomials in } k[X]. \text{ If } f \text{ is } \tau\text{-homogeneous, then } P, Q \text{ are also } \tau\text{-homogeneous, and } \deg_\tau f = \deg_\tau P - \deg_\tau Q. \text{ Moreover, if } f \text{ is } \tau\text{-homogeneous and } d(f) = 0, \text{ then } d(P) = d(Q) = 0.

\textbf{Proof.} Assume that } f \text{ is } \tau\text{-homogeneous and } \deg_\tau f = s. \text{ Then } f \text{ is homogeneous in the ordinary sense and then, by Proposition 2.10, the polynomials } P, Q \text{ are also homogeneous in the ordinary sense. Since } \tau\left(\frac{P}{Q}\right) \varepsilon^s \frac{P}{Q}, \text{ we have } \tau(P)Q = \varepsilon^s P \tau(Q) \text{ and this implies that } \tau(P) = aP, \tau(Q) = bQ, \text{ for some } a, b \in k[X] (\text{ because } P, Q \text{ are relatively prime). Comparing degrees, we deduce that } a, b \in k \setminus \{0\}. \text{ But } \tau^n \text{ is the identity map, so } P = \tau^n(P) = a^n P \text{ and } Q = \tau^n(Q) = b^n Q \text{ and so, } a, b \text{ are } n\text{-th roots of unity. Since } \varepsilon \text{ is a primitive } n\text{-root, we have } a = \varepsilon^{s_1}, b = \varepsilon^{s_2}, \text{ for some } s_1, s_2 \in \mathbb{Z}_n. \text{ Thus, the polynomials } P, Q \text{ are } \tau\text{-homogeneous, and it is clear that } s \equiv s_1 - s_2 \text{ (mod } n). \text{ Assume now that } f \text{ is } \tau\text{-homogeneous and } d(f) = 0. \text{ Then } P, Q \text{ are } \tau\text{-homogeneous Darboux polynomials of } d \text{ (with the same cofactor) and, by Proposition 5.10, we have } d(P) = d(Q) = 0. \square

Note also the following proposition

\textbf{Proposition 5.12.} If } f \in k(Y) \text{ is homogeneous, then } \circ(f) \text{ is } \tau\text{-homogeneous, and } \deg_\tau \circ(f) \equiv \deg f \text{ (mod } n).\n
\textbf{Proof.} First assume that } f = F \text{ is a nonzero homogeneous polynomial in } k[Y] \text{ of degree } s \text{ and consider all the monomial of } F. \text{ Every nonzero monomial is of the form } by^\alpha, \text{ where } 0 \neq b \in k, \text{ and } \alpha \in \mathbb{N}^n \text{ with } |\alpha| = s. \text{ For each such } y^\alpha, \text{ we have } \circ(y^\alpha) = x^\beta, \text{ where } \beta = (\beta_0, \ldots, \beta_{n-1}) = (\alpha_{n-1} - \alpha_0, \alpha_0 - \alpha_1, \alpha_1 - \alpha_2, \ldots, \alpha_{n-2} - \alpha_{n-1}), \text{ and then }

\[\sigma(\beta) = \sum_{j=0}^{n-1} j \beta_j = |\alpha| - n \alpha_{n-1} = s - n \alpha_{n-1},\]

so } \sigma(\beta) \equiv s \text{ (mod } n). \text{ This means that } \tau(x^\beta) = \varepsilon^s x^\beta. \text{ Thus, for every nonzero monomial } P, \text{ which appears in } F, \text{ we have } \tau(\circ(P)) = \varepsilon^s \circ(P). \text{ This implies that } \tau(\circ(f)) = \varepsilon^s \circ(f). \text{ But } \circ(F) \text{ is also homogeneous in the ordinary sense (because } \circ(F) \in k(X)^F, \text{ so } \circ(F) \text{ is } \tau\text{-homogeneous, and } \deg_\tau \circ(F) = \deg F \text{ (mod } n). \text{ Now let } 0 \neq f \in k(Y) \text{ be an arbitrary homogeneous rational function. Let } f = \frac{F}{G} \text{ with } F, G \in k[Y] \setminus \{0\} \text{ and } \gcd(F, G) = 1. \text{ Then } F, G \text{ are homogeneous (by Proposition 2.10), and } \circ(f) = \frac{\circ(F)}{\circ(G)}. \text{ Thus, by the above proof for polynomials, } \circ(f) \text{ is } \tau\text{-homogeneous, and } \deg_\tau \circ(f) \equiv \deg f \text{ (mod } n). \square

\textbf{Proposition 5.13.} Let } f, g \in k(Y) \text{ be homogeneous rational functions. If } \circ(f) = \circ(g), \text{ then } f = v^c g, \text{ for some } c \in \mathbb{Z}.\n
20
Lemma 5.14. A sequence \( v \) and \( \deg f = f \) rational function write this polynomial in the form □

Put: \( \beta \) to prove some lemmas and propositions \( k \) role in our description of the structure of the field \( k(X)^{d,E} \). We will show that then there exists a homogeneous (in the ordinary sense) rational function \( f \in k(Y) \) such that \( \Delta(f) = 0 \) and \( @(f) = g \). This fact will play a key role in our description of the structure of the field \( k(Y)^{\Delta} \). For a proof of this fact we need to prove some lemmas and propositions

Let us recall from Section 1, that the elements \( e_0, \ldots, e_{n-1} \in \mathbb{Z}^n \) are defined by: \( e_0 = (1,0,0,\ldots,0), e_1 = (0,1,0,\ldots,0), \ldots, e_{n-1} = (0,0,\ldots,0,1) \). In particular, we have

\[
@\langle y_j \rangle = \frac{x_{j+1}}{x_j} = x^{e_{j+1}-e_j}, \text{ for } j \in \mathbb{Z}_n.
\]

Lemma 5.14. Let \( \alpha \in \mathbb{Z}^n \). Assume that \( |\alpha| = 0 \) and \( \sigma(\alpha) = 0 \) (mod \( n \)). Then there exist a sequence \( \beta = (\beta_0, \ldots, \beta_{n-1}) \in \mathbb{Z}^n \) such that \( |\beta| = 0 \) and \( \alpha = \sum_{j=0}^{n-1} \beta_j (e_{j+1} - e_j) \).

Proof. Since \( \sigma(\alpha) \equiv 0 \mod n \), there exists an integer \( r \) such that \( n\alpha_0 + \sigma(\alpha) = -rn \).

Put: \( \beta_0 = r \) and \( \beta_j = r - \sum_{i=1}^{j} \alpha_i \), for \( j = 1, \ldots, n-1 \).

Lemma 5.15. If \( \alpha \in \mathbb{Z}^n \) with \( |\alpha| = 0 \), then there exists \( \beta \in \mathbb{Z}^n \) such that \( @(y^\beta) = x^\alpha \).

Proof. Put: \( \beta_j = \sum_{i=j+1}^{n-2} \alpha_i \) for \( j = 0, 1, \ldots, n-3 \), and \( \beta_{n-2} = 0, \beta_{n-1} = -\alpha_{n-1} \).

Now we assume that \( P \) is a fixed nonzero \( \tau \)-homogeneous polynomial in \( k[X] \). Let us write this polynomial in the form

\[
P = c_1 x^{\gamma_1} + \cdots + c_r x^{\gamma_r},
\]

where \( c_1, \ldots, c_r \) are nonzero elements of \( k \), and \( \gamma_1, \ldots, \gamma_r \in \mathbb{N}^n \). For every \( q \in \{1, \ldots, r\} \), we have \( |\gamma_q| = \deg F \) and \( \sigma(\gamma_q) \equiv \deg F \mod n \), and hence, \( |\gamma_q - \gamma_1| = 0 \) and \( \sigma(\gamma_q - \gamma_1) \equiv 0 \mod n \). This implies, by Lemma 5.14, that for any \( q \in \{1, \ldots, r\} \), there exists a sequence \( \beta(q) = (\beta_0^{(q)}, \ldots, \beta_{n-1}^{(q)}) \in \mathbb{Z}^n \) such that \( |\beta(q)| = 0 \) and

\[
\gamma_q - \gamma_1 = \sum_{j=0}^{n-1} \beta_j^{(q)} (e_{j+1} - e_j).
\]

For each \( j \in \{0, 1, \ldots, n-1\} \), we define:

\[
\alpha_j = \min \left\{ \beta_j^{(1)}, \beta_j^{(2)}, \ldots, \beta_j^{(r)} \right\},
\]

21
and we denote by $\lambda$ the sequence $(\lambda_0, \ldots, \lambda_{n-1}) \in \mathbb{Z}^n$ defined by

$$\lambda = \gamma_1 + \sum_{j=0}^{n-1} \alpha_j (e_{j+1} - e_j).$$

Observe that $|\lambda| = |\gamma_1| = \deg P$, and $\gamma_q = \lambda + \sum_{j=0}^{n-1} (\beta_j^{(q)} - \alpha_j) (e_{j+1} - e_j)$ for any $q \in \{1, \ldots, r\}$, and moreover, each $\beta_j^{(q)} - \alpha_j$ is a nonnegative integer. Put $a_{qj} = \beta_j^{(q)} - \alpha_j$, for $j \in \mathbb{Z}_n$, $q \in \{1, \ldots, r\}$, and $a_q = (a_{q0}, a_{q1}, \ldots, a_{q(n-1)})$ for all $q = 1, \ldots, r$. Then each $a_q$ belongs to $\mathbb{N}^n$, and we have the equalities

$$\gamma_q = \lambda + \sum_{j=0}^{n-1} a_{qj} (e_{j+1} - e_j), \quad \text{for any } q \in \{1, \ldots, r\}.$$

Let us remark that $\lambda \in \mathbb{N}^n$.

Indeed, for any $j \in \mathbb{Z}_n$, we have $\lambda_j = \gamma_{1j} + \alpha_{j-1} - \alpha_j$, where $\alpha_{j-1} = \beta_{j-1}^{(q)}$ for some $q$ and $\alpha_j \leq \beta_j^{(q)}$. Thus $\lambda_j = \gamma_{1j} + \beta_{j-1}^{(q)} - \alpha_j \geq \lambda_j = \gamma_{1j} + \beta_j^{(q)} - \beta_j^{(q)} = \gamma_{qj} \geq 0$.

Moreover, $|a_q| = |\beta^{(q)} - \alpha| = |\beta^{(q)}| - |\alpha| = -|\alpha|$, because $|\beta^{(q)}| = 0$. This means that $|\alpha| \leq 0$, and all the numbers $|a_1|, \ldots, |a_r|$ are the same; they are equal to $-|\alpha|$. Consider the polynomial in $k[Y]$ defined by

$$\overline{P} = c_1 y_1^{a_1} + \cdots + c_r y_r^{a_r}.$$

It is a nonzero homogeneous (in the ordinary sense) polynomial of degree $-|\alpha|$. It is easy to check that $\overline{\alpha}(\overline{P}) = x^{-\lambda} P$. Thus, we proved the following proposition.

**Proposition 5.16.** If $P \in k[X]$ is a nonzero $\tau$-homogeneous polynomial, then there exist a sequence $\lambda \in \mathbb{Z}^n$ and a homogeneous polynomial $\overline{P} \in k[Y]$ such that $\overline{\alpha}(\overline{P}) = x^{-\lambda} P$ and $|\lambda| = \deg P$.

**Remark 5.17.** In the above construction, the polynomial $\overline{P}$ is not divisible by any of the variables $y_0, \ldots, y_n$. Let us additionally assume that $d(P) = 0$. Then it is not difficult to show that $\Delta(\overline{P}) = -(\lambda_0 y_0 + \cdots + \lambda_{n-1} y_{n-1})\overline{P}$, that is, $\overline{P}$ is a strict Darboux polynomial of $\Delta$ and its cofactor is equal to $-\sum \lambda_i y_i$. This implies, by Proposition 4.1, that if additionally $d(P) = 0$, among all nonnegative numbers $\lambda_0, \ldots, \lambda_{n-1}$, at least two are different from zero.

Now we are ready to prove the following, mentioned above, proposition.

**Proposition 5.18.** Let $g$ be a $\tau$-homogeneous rational function belonging to the field $k(X)^{d,E}$. Then there exists a homogeneous rational function $f \in k(Y)$ such that $\Delta(f) = 0$ and $\overline{\alpha}(f) = g$.

**Proof.** For $g = 0$ it is obvious. Assume that $g \neq 0$, and let $g = \frac{P}{Q}$, where $P, Q \in k[X] \setminus \{0\}$ with $\gcd(P, Q) = 1$. It follows from Propositions 2.10 and 5.11, that the polynomials $P, Q$ are homogeneous (in the ordinary sense) of the same degree, and
they are also $\tau$-homogeneous. By Proposition 5.16, there exist sequences $\lambda, \mu \in \mathbb{Z}^n$ and a homogeneous polynomials $\overline{P}, \overline{Q} \in k[Y]$ such that $@ (\overline{P}) = x^{-\lambda} P$, $@ (\overline{Q}) = x^{-\mu} Q$, and $|\lambda| = |\mu| = \deg P = \deg Q$. Then we have
\[
g = \frac{P}{Q} = \frac{x^\lambda (x^{-\lambda} P)}{x^\mu (x^{-\mu} Q)} = \frac{x^\lambda @ (\overline{P})}{x^\mu @ (\overline{Q})} = x^{\lambda - \mu} @ (\overline{P}/\overline{Q}).
\]
Since $|\lambda - \mu| = 0$, there exists (by Lemma 5.15) $\beta \in \mathbb{Z}^n$ such that $@ (y^\beta) = x^{\lambda - \mu}$. Put $f = y^\beta \cdot \overline{P}/\overline{Q}$. Then $f \in k(Y)$ is a homogeneous rational function, and $@ (f) = g$.

Now we will show that $\Delta(f) = 0$. To this aim let us recall that $g$ belongs to the field $k(X)^{d,E}$, so $d(g) = 0$. This implies that $@ (\Delta(f)) = 0$, because (by Proposition 5.4) $@ (\Delta(f)) = d(@ (f)) = d(g) = 0$. But the rational function $\Delta(f)$ is homogeneous, so by Proposition 5.3, $\Delta(f) = 0$. \qed

6 Rational constants of $\Delta$

We proved (see Proposition 2.13) that $k(X)^{d,E} = k(g_1, \ldots, g_{m-1})$, where $m = n - \varphi(n)$, and $g_1, \ldots, g_{m-1} \in k(X)$ are some algebraically independent homogeneous rational functions of degree 0. We proved in fact, that each $g_j$ = (for $j = 1, \ldots, m - 1$) is equal to the quotient $\frac{w_j}{w_p}$. These quotients are usually not $\tau$-homogeneous. We will show in the next section that, in some cases, we are ready to find such algebraically independent generators of $k(X)^{d,E}$ which are additionally $\tau$-homogeneous. In this section we prove that if we have $\tau$-homogeneous generators, then we may construct some algebraically independent generators of the field $k(Y)^{\Delta}$.

Let us assume that $k(X)^{d,E} = k(g_1, \ldots, g_{m-1})$, where $g_1, \ldots, g_{m-1} \in k(X)$ are algebraically independent $\tau$-homogeneous rational functions. We know, by Proposition 5.18, that for each $g_j$ there exists a homogeneous rational function $f_j \in k(Y)$ such that $\Delta(f_j) = 0$ and $@ (f_j) = g_j$. Thus we have homogeneous rational functions $f_1, \ldots, f_{m-1}$, belonging to the field $k(Y)^{\Delta}$. We know also that $v \in k(Y)^{\Delta}$, where $v = y_0 g_1 \cdots y_{n-1}$. In this section we will prove the following theorem.

**Theorem 6.1.** Let $g_1, \ldots, g_{m-1}$ and $v, f_1, \ldots, f_{m-1}$ be as above. Then the elements $v, f_1, \ldots, f_{m-1}$ are algebraically independent over $k$, and $k(Y)^{\Delta} = k(v, f_1, \ldots, f_{m-1})$.

We will prove it in several steps.

**Step 1.** The elements $f_1, \ldots, f_{m-1}$ are algebraically independent over $k$.

**Proof.** Suppose that $W(f_1, \ldots, f_{m-1}) = 0$ for some $W \in k[t_1, \ldots, t_{m-1}]$. Then
\[
0 = @ (W(f_1, \ldots, f_{m-1})) = W( @ (f_1), \ldots, @ (f_{m-1})) = W(g_1, \ldots, g_{m-1}).
\]
But $g_1, \ldots, g_{m-1}$ are algebraically independent, so $W = 0$. \qed

In the next steps we write $f$ instead of $\{f_1, \ldots, f_{m-1}\}$, and $g$ instead of $\{g_1, \ldots, g_{m-1}\}$. In particular, $k(f)$ means $k(f_1, \ldots, f_{m-1})$. 23
Step 2. \( v \notin k(f) \).

Proof. Suppose that \( v \in k(f) \). Let \( v = P(f)/Q(f) \) for some \( P, Q \in k[t_1, \ldots, t_{m-1}] \). Then \( Q(f)v - P(f) = 0 \) and we have \( 0 = @ (Q(f)v - P(f)) = Q(g)@ (v - P(g)) \). But \( @(v) = 1 \), so \( P(g) = Q(g) \), and so \( P = Q \), because \( g_1, \ldots, g_{m-1} \) are algebraically independent. Thus \( v = P(f)/Q(f) = P(f)/P(f) = 1 \); a contradiction. \( \square \)

Step 3. The elements \( v, f_1, \ldots, f_{m-1} \) are algebraically independent over \( k \).

Proof. We already know (by Step 1) that \( f_1, \ldots, f_{m-1} \) are algebraically independent. Suppose that \( v \) is algebraic over \( k(f) \). Let \( F(t) = b_0 t^r + \cdots + b_1 t + b_0 \in k(f)[t] \) (with \( a_r \neq 0 \)) be the minimal polynomial of \( v \) over \( k(f) \). Multiplying by the common denominator, we may assume that the coefficients \( b_0, \ldots, b_r \) belong to the ring \( k[f] \). There exists polynomials \( B_0, B_1, \ldots, B_r \in k[t_1, \ldots, t_{m-1}] \) such that \( b_j = B_j(f) \) for all \( j = 0, \ldots, r \). Thus, \( B_r(f)v^r + \cdots + B_1(f)v + B_0(f) = 0 \). Using \( @ \), we obtain the equality

\[
B_r(g)1^r + \cdots + B_1(g)1 + B_0(g) = 0,
\]

which implies that \( B_r + \cdots + B_1 + B_0 = 0 \), because \( g_1, \ldots, g_{m-1} \) are algebraically independent over \( g \). This means, in particular, that \( F(1) = 0 \). But \( F(t) \) is an irreducible polynomial of degree \( r \geq 1 \), so \( r = 1 \). Hence, \( B_1(f)v + B_0(f) = 0 \), \( B_1(f) \neq 0 \), and hence \( v = -B_0(f)/B_1(f) \in k(f) \); a contradiction with Step 2. \( \square \)

It is clear that \( v(f, f) \subseteq k(Y)^\Delta \). For a proof of Theorem 6.1 we must show that the reverse inclusion also holds. Note that the derivation \( \Delta \) is homogeneous, so it is well known that its field of constants is generated by some homogeneous rational functions. Hence for a proof of this theorem we need to prove that every homogeneous element of \( k(Y)^\Delta \) is an element of \( k(v, f) = k(v, f_1, \ldots, f_{m-1}) \).

Let us assume that \( H \) is a nonzero homogeneous rational function belonging to \( k(Y)^\Delta \), and put \( h = @ (H) \).

Step 4. \( h \in k(g) \) and \( h \) is \( \tau \)-homogeneous.

Proof. Since \( h = @ (H) \), we have \( h \in k(X)^E \). Moreover, \( d(h) = d@ (H) = @ \Delta (H) = @ (0) = 0 \), so \( h \in k(X)^d \cap k(X)^E = k(X)^{d,E} = k(g) \). The \( \tau \)-homogeneity of \( h \) follows from Proposition 5.12. \( \square \)

Now we introduce some new notations. The \( \tau \)-degrees of \( g_1, \ldots, g_{m-1} \) we denote by \( s_1, \ldots, s_{m-1} \), respectively, and by \( s \) we denote the \( \tau \)-degree of \( h \). Thus we have \( \tau (g_j) = \varepsilon^s g_j \) for \( j = 1, \ldots, m-1 \), and \( \tau (h) = \varepsilon^s h \). We already know that \( h \in k(g) \), so we have

\[
h = \frac{A(g)}{B(g)}
\]

for some relatively prime nonzero polynomials \( A, B \in k[t_1, \ldots, t_{m-1}] \).

Step 5. The elements \( A(g), B(g) \) are \( \tau \)-homogeneous.

Proof. Since \( \tau (h) = \varepsilon^s h \), we have \( \tau (A(g))B(g) = \varepsilon^s A(g)\tau (B(g)) \), that is,

\[
A(\varepsilon^s g_1, \ldots, \varepsilon^{s_{m-1}} g_{m-1})B(g_1, \ldots, g_{m-1}) = \varepsilon^s A(g_1, \ldots, g_{m-1})B(\varepsilon^{s_1} g_1, \ldots, \varepsilon^{s_{m-1}} g_{m-1})
\]

24
But the elements \( g_1, \ldots, g_{m-1} \) are algebraically independent over \( k \), so in the polynomial ring \( k[t_1, \ldots, t_{m-1}] \) we have the equality
\[
A\left(\varepsilon^{s_1}t_1, \ldots, \varepsilon^{s_{m-1}}t_{m-1}\right) \cdot B = \varepsilon^s A \cdot B\left(\varepsilon^{s_1}t_1, \ldots, \varepsilon^{s_{m-1}}t_{m-1}\right),
\]
which implies that \( A\left(\varepsilon^{s_1}t_1, \ldots, \varepsilon^{s_{m-1}}t_{m-1}\right) = pA \) and \( B\left(\varepsilon^{s_1}t_1, \ldots, \varepsilon^{s_{m-1}}t_{m-1}\right) = qB \), for some \( p, q \in k[t_1, \ldots, t_{m-1}] \) (because we assumed that \( \gcd(A, B) = 1 \)). Comparing degrees we deduce that \( p, q \in k \). Therefore, \( \tau(A(g)) = A(\tau(g_1, \ldots, \tau(g_{m-1})) = A\left(\varepsilon^{s_1}g_1, \ldots, \varepsilon^{s_{m-1}}g_{m-1}\right) = pA(g_1, \ldots, g_{m-1}) = pA(g) \), so, \( \tau(A(g)) = pA(g) \), and similarly \( \tau(B(g)) = qB(g) \). But \( \tau^n \) is the identity map, so \( p^n = q^n = 1 \) and so, \( p, q \) are \( n \)-th roots of unity. Put \( p = \varepsilon^a \) and \( q = \varepsilon^b \), where \( a, b \in \mathbb{Z}_n \). Then we have \( \tau(A(g)) = \varepsilon^a A(g) \) and \( \tau(B(g)) = \varepsilon^b B(g) \). Moreover, \( A(g), B(g) \) are homogeneous in the ordinary sense, because they belong to \( k(X)^E \), so they are homogeneous rational functions of degree zero. This means that \( A(g), B(g) \) are \( \tau \)-homogeneous. □

Let us fix: \( a = \deg_{\tau} A(g) \) and \( b = \deg_{\tau} B(g) \).

If \( \alpha = (\alpha_1, \ldots, \alpha_{m-1}) \in \mathbb{N}^{m-1} \), then, as usually, we denote by \( t^\alpha \) and \( g^\alpha \) the elements \( t_1^{\alpha_1} \cdots t_{m-1}^{\alpha_{m-1}} \) and \( g_1^{\alpha_1} \cdots g_{m-1}^{\alpha_{m-1}} \), respectively, and moreover, we denote:
\[
\begin{align*}
   w(\alpha) &= \alpha_1 \cdot s_1 + \cdots + \alpha_{m-1} \cdot s_{m-1}, \\
   u(\alpha) &= \alpha_1 \cdot \deg f_1 + \cdots + \alpha_{m-1} \cdot \deg f_{m-1}.
\end{align*}
\]
Recall that \( s_j = \deg_{\tau}(g_j) \) and \( \oplus(f_j) = g_j \), for all \( j = 1, \ldots, m-1 \). It follows from Proposition 5.12 that for each \( j \) we have the congruence \( s_j \equiv \deg f_j \pmod n \). Therefore,
\[ u(\alpha) \equiv w(\alpha) \pmod n \quad \text{for all} \quad \alpha \in \mathbb{N}^{m-1}. \]

Let us write the polynomials \( A, B \) in the forms
\[
A = \sum_{\alpha \in S_A} A_\alpha t^\alpha, \quad B = \sum_{\beta \in S_B} B_\beta t^\beta,
\]
where \( A_\alpha, B_\beta \) are nonzero elements of \( k \), and \( S_A, S_B \) are finite subsets of \( \mathbb{N}^{m-1} \).

**Step 6.** \( w(\alpha) \equiv a \pmod n \) for all \( \alpha \in S_A \), and \( w(\beta) \equiv b \pmod n \) for all \( \beta \in S_B \).

**Proof.** Since \( \tau(A(g)) = \varepsilon^a A(g) \), we have
\[
\varepsilon^a \sum A_\alpha g^\alpha = \varepsilon^a A(g) = \tau(A(g)) = \sum A_\alpha \tau(t^\alpha) = \sum A_\alpha (\varepsilon^{s_1}g_1)^{\alpha_1} \cdots (\varepsilon^{s_{m-1}}g_{m-1})^{\alpha_{m-1}} = \sum A_\alpha \varepsilon^{u(\alpha)} g^\alpha.
\]
Hence, \( \sum A_\alpha (\varepsilon^a - \varepsilon^{u(\alpha)}) g^\alpha = 0 \). But \( g_1, \ldots, g_{m-1} \) are algebraically independent and each \( A_\alpha \) is nonzero, so \( \varepsilon^{u(\alpha)} = \varepsilon^a \) and consequently \( w(\alpha) \equiv a \pmod n \), for all \( \alpha \in S_A \). The same we do for the elements \( w(\beta) \). □
Since $u(\alpha) \equiv w(\alpha) \pmod{m}$ for all $\alpha \in \mathbb{N}^{m-1}$, it follows from the above step that, for each $\alpha \in S_A$, there exists $p(\alpha) \in \mathbb{Z}$ such that $u(\alpha) = a + p(\alpha)n$. Put

$$p = \max (\{0\} \cup \{p(\alpha); \alpha \in S_A\}),$$

and put $a(\alpha) = p - p(\alpha)$ for $\alpha \in S_A$. Then all $a(\alpha)$ are nonnegative integers and all the numbers $u(\alpha) + a(\alpha)n$, for each $\alpha \in S_A$, are the same; they are equal to $a + pn$.

A similar procedure we do with elements of $S_B$. For each $\beta \in S_B$ there exists an integer $b(\beta)$ such that $u(\beta) + b(\beta)n = b + qn$, for all $\beta \in S_B$, where $q$ is a nonnegative integer. Consider now the following quotient

$$\Theta = \frac{\sum_{\alpha \in S_A} A_{\alpha} f^{a(\alpha)} A_s}{\sum_{\beta \in S_B} B_{\beta} f^{b(\beta)} A_s}.$$ 

This quotient belongs of course to $k(v, f_1, \ldots, f_{n-1})$. In its numerator each component $A_s f^{a(\alpha)}$, for all $\alpha \in S_A$, is a homogeneous rational function of the same degree $a + pn$, so the numerator is homogeneous. By the same way we see that the denominator is also homogeneous. Hence, $\Theta$ is a homogeneous rational function. Observe that $@(\Theta) = h$. We have also $@(H) = h$. Thus, $H$ and $\Theta$ are two homogeneous rational functions such that $H = v^c \cdot \Theta$. By Proposition 5.13, there exists an integer $c$ such that $H = v^c \cdot \Theta$.

Therefore, $H \in k(v, f_1, \ldots, f_{n-1})$. This completes our proof of Theorem 6.1. □

7 Two special cases

In this section we present a description of the field $k(Y)^\Delta$ in the case when $s$ is a power of a prime number, and in the case when $n$ is a product of two primes.

Let $n = p^s$, where $p$ is prime and $s \geq 1$. We already know, by Theorem 5.6, that if $s = 1$, then $k(Y)^\Delta = k(v)$. Now we assume that $s \geq 2$.

**Theorem 7.1.** If $n = p^s$, where $p$ is prime and $s \geq 2$, then

$$k(Y)^\Delta = k(v, f_1, \ldots, f_{m-1})$$

with $m = p^{s-1}$, where $v = y_0 \cdots y_{n-1}$ and $f_1, \ldots, f_{m-1} \in k(Y)$ are homogeneous rational functions such that $v, f_1, \ldots, f_{m-1}$ are algebraically independent over $k$.

**Proof.** In this case $m = n - \varphi(n) = p^s - \varphi(p^s) = p^{s-1}$ and hence, $n = pm$. Since $\Phi_p(t) = 1 + t^m + t^2m + \cdots + t^{(p-1)m}$, we have: $w_0 = u_0 u_m u_{2m} \cdots u_{(p-1)m}$, and $w_j = u_{0m+j} u_{1m+j} u_{2m+j} \cdots u_{(p-1)m+j}$, for all $j = 0, 1, \ldots, m - 1$. Recall (see Lemma 1.1) that $\tau(u_j) = u_{j+1}$ for $j \in \mathbb{Z}_n$, so each $w_j$ is equal to $\tau^j(w_0)$.

Observe that $\tau^m(w_0) = w_0$. This implies that the $\tau$-degree of every nonzero monomial (with respect to variables $x_0, \ldots, x_{n-1}$) of $w_0$ is divisible by $p$. This means that in the $\tau$-decomposition of $w_0$ there are only components with $\tau$-degrees 0, $p, 2p, \ldots, (m - 1)p$. Let $w_0 = v_0 + v_1 + \cdots + v_{m-1}$, where each $v_j \in k[X]$ is $\tau$-homogeneous and $\tau(v_j) = \varepsilon^j v_j$. Of
course \( d(v_j) = 0 \) for all \( j \) (because \( \tau d = \varepsilon d\tau \)), and \( \deg(v_j) = p \) for all \( j \) (by Proposition 2.7).

Now observe that if \( p \geq 3 \) then \( \mathcal{g}(w_0) = w_0 \), and if \( p = 2 \) then \( \mathcal{g}(w_0) = -w_0 \). Hence \( \mathcal{g}(w_0) = \pm w_0 \), and we have

\[
v_0 + v_1 + \cdots + v_{m-1} = w_0 = \pm \mathcal{g}(w_0) = \pm (\mathcal{g}(v_0) \pm \mathcal{g}(v_1) \pm \cdots \pm \mathcal{g}(v_{m-1})
\]

Since the \( \tau \)-decomposition of \( w_0 \) is unique, we deduce (by Proposition 5.7), that

\[
v_1 = \pm \mathcal{g}(v_0), \quad v_2 = \pm \mathcal{g}(v_1), \quad \ldots, \quad v_{m-1} = \pm \mathcal{g}(v_{m-2}), \quad v_0 = \pm \mathcal{g}(v_{m-1}),
\]

and we have \( v_j = \pm \mathcal{g}^j(v_0) \) for all \( j = 0, 1, \ldots, m-1 \). Therefore, the \( \tau \)-decomposition of \( w_0 \) is of the form \( w_0 = v_0 + b_1 \mathcal{g}(v_0) + b_2 \mathcal{g}^2(v_0) + \cdots + b_{m-1} \mathcal{g}^{m-1}(v_0) \), where the coefficients \( b_1, \ldots, b_{m-1} \) belong to \( \{ -1, 1 \} \). This implies that

\[
w_0 = \tau(w_0) = v_0 + b_1 \varepsilon^p \mathcal{g}(v_0) + b_2 \varepsilon^{2p} \mathcal{g}^2(v_0) + \cdots + b_{m-1} \varepsilon^{(m-1)p} \mathcal{g}^{m-1}(v_0).
\]

We do the same for \( w_2 = \tau(w_1) = \tau^2(w_0) \), and for all \( w_j \). Thus, for all \( j = 0, 1, \ldots, m-1 \), we have \( w_j = v_0 + c_{j1} \mathcal{g}(v_0) + c_{j2} \mathcal{g}^2(v_0) + \cdots + c_{j,m-1} \mathcal{g}^{m-1}(v_0) \), where each \( c_{ji} \) belongs to the ring \( \mathbb{Z}[\varepsilon] \). Consider now the rational functions \( g_1, \ldots, g_{m-1} \in k(X) \) defined by

\[
g_j = \frac{\mathcal{g}^j(v_0)}{v_0},
\]

for \( j = 1, \ldots, m-1 \). These functions are \( \tau \)-homogeneous. They are homogenous of degree zero, and they are constants of \( d \). Moreover, if \( j \in \{ 1, \ldots, m-1 \} \), then we have:

\[
\frac{w_j}{w_0} = \frac{v_0 + \sum_{i=1}^{m-1} c_{ji} \mathcal{g}^i(v_0)}{v_0 + \sum_{i=1}^{m-1} c_{0i} \mathcal{g}^i(v_0)} = \frac{1 + v_0^{-1} \sum_{i=1}^{m-1} c_{ji} \mathcal{g}^i(v_0)}{1 + v_0^{-1} \sum_{i=1}^{m-1} c_{0i} \mathcal{g}^i(v_0)} = \frac{1 + \sum_{i=1}^{m-1} c_{ji} g_i}{1 + \sum_{i=1}^{m-1} c_{0i} g_i}.
\]

Hence, all the elements \( \frac{w_1}{w_0}, \ldots, \frac{w_{m-1}}{w_0} \) belong to the field \( k(g_1, \ldots, g_{m-1}) \), and hence, by Proposition 2.13, the elements \( g_1, \ldots, g_{m-1} \) are algebraically independent over \( k \) and we have the equality \( k(X)^{E,d} = k(g_1, \ldots, g_{m-1}) \). Note that \( g_1, \ldots, g_{m-1} \) are \( \tau \)-homogeneous. It follows from Proposition 5.18, that for each \( g_j \) there exists a homogeneous rational function \( f_j \in k(Y) \) such that \( \Delta(f_j) = 0 \) and \( \@ (f_j) = g_j \). We know, by Theorem 6.1, that the elements \( v, f_1, \ldots, f_{m-1} \), are algebraically independent over \( k \), and \( k(Y)^\Delta = k(v, f_1, \ldots, f_{m-1}) \). This completes our proof of Theorem 7.1. \( \square \)

Using the above theorem and its proof we obtain:

**Example 7.2.** If \( n = 4 \), then \( k(Y)^\Delta = k(v, f) \), where \( f = y_1 y_9^2 - y_2 y_9 + y_3 y_9 - y_4 y_9 \) and \( v = y_0 y_1 y_2 y_3 \).

Consider the case \( n = 6 \).

**Example 7.3.** If \( n = 6 \), then \( k(Y)^\Delta = k(v, f_1, f_2, f_3) \), where \( v = y_0 \cdots y_5 \), and \( f_1, f_2, f_3 \) are some homogeneous rational functions in \( k(Y) \) such that \( v, f_1, f_2, f_3 \) are algebraically independent over \( k \).
Proof. We have: \( \varphi(n) = \varphi(6) = 2, \ m = n - \varphi(n) = 4, \ \Phi_6(t) = t^2 - t + 1, \) and \( w_0 = \frac{u_0 u_2}{u_1}, \ w_1 = \frac{u_1 u_3}{u_2} = \tau(w_0), \ w_2 = \frac{u_2 u_4}{u_3} = \tau^2(w_0), \ w_3 = \frac{u_3 u_5}{u_4} = \tau^3(w_0). \) Let us denote: \( F_0 = u_0u_2u_4, \ F_1 = u_1u_3u_5 = \tau(F_0), \ G_0 = u_0u_3, \ G_1 = u_1u_4 = \tau(G_0), \ G_2 = u_2u_5 = \tau^2(G_0) \). It is clear that the polynomials \( F_0, F_1, G_0, G_1, G_2 \) are constants of \( d \). Note that \( w_0 = \frac{F_0}{G_1}, \ w_1 = \frac{F_1}{G_2}, \ w_2 = \frac{F_0}{G_0}, \ w_3 = \frac{F_1}{G_1}, \) so we have: \( \frac{w_1}{w_0} = \frac{F_1G_0}{F_0G_2}, \ \frac{w_2}{w_0} = \frac{F_0G_1}{F_0G_0} = G_0 \), \( \frac{w_3}{w_0} = \frac{F_1G_0}{G_2G_1} = F_0 \).

Observe that \( \tau^2(F_0) = F_0 \). This implies that the \( \tau \)-degree of every nonzero monomial (with respect to variables \( x_0, \ldots, x_{n-1} \)) of \( F_0 \) is divisible by 3. This means that in the \( \tau \)-decomposition of \( F_0 \) there are only components with \( \tau \)-degrees 0 and 3. Let \( F_0 = v_0 + v_3 \), where \( v_0 \in k[X] \) is \( \tau \)-homogeneous with \( \deg_{\tau}(v_0) = 0 \) (that is, \( \tau(v_0) = v_0 \)), and \( v_3 \in k[X] \) is \( \tau \)-homogeneous with \( \deg_{\tau}(v_3) = 3 \) (that is, \( \tau(v_3) = \varepsilon^3(v_3) = -v_3 \)). Of course \( d(v_0) = d(v_3) = 0 \). Observe that \( \varrho(F_0) = F_0 \). Hence, \( v_0 + v_3 = F_0 = \varrho(F_0) = \varrho(v_0) + \varrho(v_3) \).

Since the \( \tau \)-decomposition of \( F_0 \) is unique, we deduce (by Proposition 5.7), that \( v_3 = \varrho(v_0) \) and \( v_0 = \varrho(v_3) \), and so, the \( \tau \)-decomposition of \( F_0 \) is of the form \( F_0 = v_0 + \varrho(v_0) \). Moreover, \( F_1 = \tau(F_0) = \tau(v_0) + \tau(\varrho(v_0)) = v_0 + \varepsilon^2 \varrho(v_0) = v_0 - \varrho(v_0) \).

We do a similar procedure with the polynomial \( G_0 \). We first observe that \( \tau^2(G_0) = G_0 \), and \( \varrho(G_0) = -G_0 \), and then we obtain the following three \( \tau \)-decompositions: \( G_0 = r_0 - \varrho(r_0) + \varepsilon^2 r_0, \ G_1 = r_0 - \varepsilon^2 \varrho(r_0) + \varepsilon \varrho^2(r_0), \ G_2 = r_0 - \varepsilon^4 \varrho(r_0) + \varepsilon^2 \varrho^2(r_0), \) where \( r_0 \) is \( \tau \)-homogeneous polynomial of degree 2 which is \( \tau \)-homogeneous of \( \tau \)-degree zero. Consider now the rational functions \( g_1, g_2, g_3 \in k(X) \) defined by \( g_1 = \frac{\varrho(v_0)}{v_0}, \ g_2 = \frac{\varrho(r_0)}{r_0}, \ g_3 = \frac{\varrho^2(r_0)}{r_0} \).

These functions are \( \tau \)-homogeneous. They are homogeneous of degree zero (in the ordinary sense) and they are constants of \( d \). Moreover, the quotients \( \frac{w_1}{w_0}, \ \frac{w_2}{w_0}, \ \frac{w_3}{w_0}, \) belong to \( k(g_1, g_2, g_3) \). In fact:

\[
\frac{w_1}{w_0} = \frac{F_1G_0}{F_0G_2} = \frac{(\varrho(v_0))(\varrho(r_0) - \varepsilon^2 \varrho(r_0) + \varepsilon \varrho^2(r_0))}{(\varrho(v_0))(\varrho(r_0) - \varepsilon^2 \varrho(r_0) + \varepsilon \varrho^2(r_0))} = \frac{1}{(1-g_1)(1-\varepsilon^2 g_2 + \varepsilon^4 g_3)}
\]

and so, \( \frac{w_1}{w_0} \in k(g_1, g_2, g_3) \). By a similar way we show that \( \frac{w_2}{w_0} \) and \( \frac{w_3}{w_0} \) also belong to \( k(g_1, g_2, g_3) \). Hence, by Proposition 2.13, the elements \( g_1, g_2, g_3 \) are algebraically independent over \( k \) and \( k(X)^{E,d} = k(g_1, g_2, g_3) \). It follows from Proposition 5.18, that for each \( g_j \) there exists a homogeneous rational function \( f_j \in k(Y) \) such that \( \Delta(f_j) = 0 \) and \( @(f_j) = g_j \). We know, by Theorem 6.1, that the elements \( v, f_1, f_2, f_3 \), are algebraically independent over \( k \), and \( k(Y)^{E} = k(v, f_1, f_2, f_3) \).

Now we assume that \( p > q \) are primes, and \( n = pq \). In the above proof we used the explicit form of the cyclotomic polynomial \( \Phi_p(t) \). Let \( \Phi_{pq} = \sum c_j t^j \). In 1883, Migotti [19] showed that all \( c_j \) belong to \( \{-1, 0, 1\} \). In 1964 Beiter [1] gave a criterion on \( j \) for \( c_j \) to be 0, 1 or -1. A similar result, but more elementary, gave in 1996, Lam and Leung [11].
Their criterion is based on the fact that \( \varphi(pq) = (p-1)(q-1) \) can be expressed uniquely in the form \( rp + sq \) where \( r, s \) are nonnegative integers. Thus, we have the equality

\[
\varphi(pq) = rp + sq \quad \text{with} \quad r, s \in \mathbb{N}.
\]

The numbers \( r, s \) are uniquely determined, and it is clear that \( 0 \leq r \leq q-2, \ 0 \leq s \leq p-2, \ r = r_1 - 1 \) and \( s = s_1 - 1 \), where \( r_1 \in \{1, \ldots, q-1\}, \ s_1 \in \{1, \ldots, p-1\} \) such that \( r_1 p \equiv 1 \pmod{q} \) and \( s_1 q \equiv 1 \pmod{p} \). Using the numbers \( r, s \), Lam and Leung proved:

**Lemma 7.4 ([11]).** Let \( \Phi_{pq}(t) = \sum_{k=0}^{\varphi(pq)} c_k t^k \). Then

- \( c_k = 1 \iff k = ip + jq, \ i \in \{0, 1, \ldots, r\}, \ j \in \{0, 1, \ldots, s\} \);
- \( c_k = -1 \iff k = ip + jq + 1, \ i \in \{0, 1, \ldots, (q-2) - r\}, \ j \in \{0, 1, \ldots, (p-2) - s\} \).

Now we may prove the following theorem.

**Theorem 7.5.** If \( n = pq \) where \( p > q \) are primes, then

\[
k(Y)^{\Delta} = k(v, f_1, \ldots, f_{m-1})
\]

with \( m = p + q - 1 \), where \( v = y_0 \cdots y_{n-1} \) and \( f_1, \ldots, f_{m-1} \in k(Y) \) are homogeneous rational functions such that \( v, f_1, \ldots, f_{m-1} \) are algebraically independent over \( k \).

**Proof.** We use the same idea as in the proofs of Theorem 7.1 and Example 7.3. We have: \( \varphi(n) = (p-1)(q-1) \) and \( m = n - \varphi(n) = p + q - 1 \). For each \( i \in \mathbb{Z} \), let us denote:

\[
F_i = \prod_{j=0}^{p-1} u_{jq+i}, \quad G_i = \prod_{j=0}^{q-1} u_{jp+i}.
\]

In particular, \( F_0 = u_0 u_2 u_4 \cdots u_{(p-1)q} \) \( G_0 = u_0 u_p u_{2p} \cdots u_{(q-1)p} \). Observe that if \( i = bq + c \), where \( b, c \in \mathbb{Z} \) and \( 0 \leq c < q \), then \( F_i = F_c \). Similarly, if \( i = bp + c \), where \( b, c \in \mathbb{Z} \) and \( 0 \leq c < p \), then \( G_i = G_c \). Let \( A \) be the set of all indexes \( k \in \{0, 1, \ldots, \varphi(pq)\} \) with \( c_k = 1 \), and let \( B \) be the set of all indexes \( k \in \{0, 1, \ldots, \varphi(pq)\} \) with \( c_k = -1 \). It is clear that \( A \cap B = \emptyset, A \neq \emptyset, B \neq \emptyset, \) and \( w_0 = \frac{N}{D} \) where \( N = \prod_{k \in A} u_k, \ D = \prod_{k \in B} u_k \). It follows from Lemma 7.4, that

\[
N = \prod_{i=0}^{r} \prod_{j=0}^{s} u_{ip+jq}, \quad D = \prod_{i=0}^{(q-2)-r} \prod_{j=0}^{(p-2)-s} u_{ip+jq+1}.
\]

It is easy to check that \( \prod_{i=0}^{r} F_i \cdot p^{r-1} \cdot s \) \( \prod_{j=0}^{p-2-s} G_{jq+1} \cdot D \cdot T \), where

\[
S = \prod_{i=0}^{r} \prod_{j=s+1}^{p-1} u_{ip+jq} \quad \text{and} \quad T = \prod_{j=0}^{p-2-s} \prod_{i=q-r+1}^{q-1} u_{ip+jq+1}.
\]

Now we will show that \( S = T \). First observe that \( S \) and \( T \) have the same number of factors, which is equal to \( (r + 1)(p - s - 1) \). Next observe that

\[
S = \prod_{i=0}^{r} \prod_{j=0}^{p-s-2} u_{ip+(s+1+j)q} \quad \text{and} \quad T = \prod_{j=0}^{p-2-s} \prod_{i=0}^{r} u_{(q-r+1+i)p+jq+1}.
\]
Thus, it is enough to show that, that for $i \in \{0, \ldots, r\}$ and $j \in \{0, 1, \ldots, p - s - 2\}$, we have $(s + 1 + j)q + jq \equiv (q - r - 1 + i)p + jq + 1 \pmod{pq}$. But it is obvious, because $(p - 1)(q - 1) = rp + sq$. Therefore, $S = T$ and we have

$$(*) \quad w_0 = \frac{\prod_{i=0}^r F_{ij}^{ip}}{\prod_{j=0}^{p-2-s} G_{jq+1}}.$$

Now we do exactly the same as in the proof of Example 7.3. We have the homogeneous polynomials $F_0, \ldots, F_{q-1}$ and $G_0, \ldots, G_{p-1}$, which are constants of $d$, and $F_i = \tau^i(F_0)$, $G_i = \tau^i(G_0)$, deg $F_i = p$, deg $G_i = q$, for each $i$. Observe that $\tau^q(F_0) = F_0$. This implies that the $\tau$-degree of every nonzero monomial (with respect to variables $x_0, \ldots, x_{n-1}$) of $F_0$ is divisible by $p$. This means that in the $\tau$-decomposition of $F_0$ there are only components with $\tau$-degrees $0, 2p, \ldots, (q - 1)p$. Let $F_0 = \sum_{i=0}^{q-1} v_i$, where each $v_i$ is a $\tau$-homogeneous polynomial from $k[X]$, and $\tau(v_i) = \varepsilon^p v_j$. Of course $d(v_i) = 0$ for all $i$ (because $\tau d = \varepsilon d\tau$), and deg$(v_i) = p$. But $\varrho(u_j) = \varepsilon^{-j} u_j$ (see Lemma 1.1), so $\varrho(F_0) = \pm F_0$, and we have

$$v_0 + v_1 + \cdots + v_{m-1} = F_0 = \pm \varrho(F_0) = \pm (\varrho(v_0) \pm \varrho(v_1) \pm \cdots \pm \varrho(v_{m-1}))$$

Since the $\tau$-decomposition of $F_0$ is unique, we deduce (by Proposition 5.7), that $v_1 = \pm \varrho(v_0)$, $v_2 = \pm \varrho(v_1)$, $\ldots$, $v_{m-1} = \pm \varrho(v_{m-2})$, $v_0 = \pm \varrho(v_{m-1})$, and we have $v_j = \pm \varrho^j(v_0)$ for all $j = 0, 1, \ldots, q - 1$.

Therefore, the $\tau$-decomposition of $F_0$ is of the form $F_0 = v_0 + \sum_{i=1}^{q-1} b_i \varrho^i(v_0)$, where $b_1, \ldots, b_{m-1} \in \{-1, 1\}$. This implies that $F_1 = \tau(F_0) = v_0 + \sum_{i=1}^{q-1} b_i \varrho^i(v_0)$. We do the same for $F_2 = \tau(F_1) = \tau^2(F_0)$, and for all $F_j$. Thus, for all $j = 0, 1, \ldots, m - 1$, we have

$$F_j = v_0 + \sum_{i=1}^{q-1} c_{ji} \varrho^i(v_0),$$

where each $c_{ji}$ belongs to the ring $\mathbb{Z} \varepsilon$. We do a similar procedure with the polynomial $G_0$. First observe that $\tau^p(G_0) = G_0$ and $\varrho(G_0) = \pm G_0$, and then we obtain $\tau$-decompositions of the forms

$$G_j = r_0 + \sum_{i=1}^{p-1} b_{ji} \varrho^i(r_0),$$

where each $c_{ji}$ belongs to $\mathbb{Z} \varepsilon$, where $r_0$ is a homogeneous polynomial of degree $q$ which is $\tau$-homogeneous of $\tau$-degree zero.

Consider now the elements $g_1, \ldots, g_{m-1} \in k(X)$ defined by

$$g_i = \frac{\varrho^i(v_0)}{v_0}, \quad g_{q-1+j} = \frac{\varrho^j(r_0)}{r_0},$$

for $i = 1, \ldots, q - 1$, and $j = 1, \ldots, p - 1$. These elements are $\tau$-homogeneous. They are homogeneous of degree zero (in the ordinary sense) and they are constants of $d$. We know, by the above construction, that each element of the form $\frac{1}{v_0} \tau^i(F_j)$ or $\frac{1}{r_0} \tau^i(G_j)$ belongs to the field $k(g_1, \ldots, g_{m-1})$. But, by $(*)$, for each $a = 0, \ldots, m - 1$, we have

$$w_a \frac{v_0^{p-1-s}}{v_0^{r+1}} = \tau^a(w_0) \frac{r_0^{p-1-s}}{r_0^{r+1}} = \frac{\prod_{i=0}^r \tau^a(F_{ip})}{\tau^a(v_0)} \frac{\prod_{j=0}^{p-2-s} \tau^a(G_{jq+1})}{\tau^a(r_0)}.$$
and hence, each element $w_j v_0^{p-1-s} u_0^{-(r+1)}$ belongs to $k(g_1, \ldots, g_{m-1})$. This implies, that for every $j = 1, \ldots, m-1$, the quotient

$$\frac{w_j}{w_0} = \frac{v_0^{p-1-s} u_0^{-(r+1)} w_j}{v_0^{p-1-s} u_0^{-(r+1)} w_0}$$

belongs to $k(g_1, \ldots, g_{m-1})$. Hence, by Proposition 2.13, the elements $g_1, \ldots, g_m$ are algebraically independent over $k$ and $k(X)^E, d = k(g_1, \ldots, g_{m-1})$. It follows from Proposition 5.18, that for each $g_j$ there exists a homogeneous rational function $f_j \in k(Y)$ such that $\Delta(f_j) = 0$ and $\Delta(f_j) = g_j$. We know, by Theorem 6.1, that the elements $v, f_1, \ldots, f_{m-1}$, are algebraically independent over $k$, and $k(Y)^\Delta = k(v, f_1, \ldots, f_{m-1})$. This completes our proof of Theorem 7.5. □

We already know a structure of the field $k(Y)^\Delta$ but only in the following two cases, when $n$ is a power of a prime number (Theorem 7.1), and when $n$ is the product of two prime numbers (Theorem 7.5). We do not know what happens in all other cases. Is this field always a purely transcendental extension of $k$? What is in the cases $n = 12$ or $n = 30$ or $n = 105$?
